Abstract

We study the ultraviolet problem for quantum electrodynamics on a three dimensional torus. We start with the lattice gauge theory on a toroidal lattice and seek to control the singularities as the lattice spacing is taken to zero. This is done by following the flow of a sequence of renormalization group transformations. The analysis is facilitated by splitting the space of gauge fields into into large fields and small fields at each step following Balaban. In this paper we explore the first step in detail.

1 Introduction

Quantum electrodynamics in a four dimensional space time, $(\mathrm{QED})_4$, is the basic theory of electrons and photons. The theory is very singular at short distances. Nevertheless it does have a well defined perturbation theory (expansion in the coupling constant) provided various renormalizations are carried out. At this level it gives a spectacularly precise description of nature.

One would like to have a rigorous non-perturbative construction of the model. To date this has not been possible and success is not likely anytime soon. However the singularities are weaker in lower dimensions and there is the possibility of progress. In this sequence of papers we give a construction of $(\mathrm{QED})_3$. To avoid long distance (infrared) problems, which are also present, we work on the three dimensional torus.

The theory is formally defined by functional integrals. The program is to add cutoffs to take out the short distance (ultraviolet) singularities and make the theory well-defined. Then one tries to remove the cutoffs. The singularities that develop are to be cancelled by adjusting the bare parameters - this is renormalization. At the same time one must keep control throughout over the size of the functional integrals - this is the stability problem.

An effective way to deal with these difficulties is to regularize the theory by putting it on a lattice and then study the continuum limit. [1] This regularization has the advantage of preserving gauge invariance. This helps with the treatment of the singularities- the counterterms required are minimal. The stability problem also seems more tractable in the lattice approximation.

Our general method is the renormalization group (RG) technique. We first scale up to a unit lattice theory. By block averaging we generate a sequence of effective actions corresponding to different length scales. The effective coupling constant starts from near zero and grows but remains small. Renormalization cancellations are made perturbatively at each level. The remainders must also be controlled and for this we need control over the size of the gauge field. This is accomplished by breaking the functional integral into large and small field regions at each level. The contribution of the large field region is suppressed by the free measure, and in the small field region we can do the perturbative analysis. Stability emerges naturally in this approach as well.

The scheme outlined above was originally developed by Balaban for a study of scalar $(\mathrm{QED})_3$ [1], [2], [3], [4]. See also King [21]. The method was further developed by Balaban, Brydges, Imbrie, and Jaffe [7], [8] who used it in their study of the Higgs mechanism for this model. There is further exposition of this work in lecture notes by Imbrie [20]. Balaban continued by proving basic stability bounds for pure Yang-Mills YM_3, YM_4 [5],[6]. Balaban, O'Carroll, and Schor [9], [10] gave an analysis of the fermion propagators that arise in a RG approach. These papers were the main inspiration for the present work.

---

[1] An alternative would be to work with a continuum theory and put in explicit momentum cutoffs. For a discussion of this approach to gauge field theories see Magnen, Rivasseau, and Seneor [23]

Let us also mention some earlier related results. Weingarten and Challifour [25] and Weingarten [26] gave a construction of $(\mathrm{QED})_2$. For scalar electrodynamics there is extensive work for $d = 2$ by Brydges, Fröhlich, and Seiler [13]. Magnen and Seneor gave a treatment of Yukawa in $d = 3$ [22]. For a heuristic discussion of $(\mathrm{QED})_3$ see [14].

The present work will not directly generalize to $(\mathrm{QED})_4$. The problem is that this model lacks ultraviolet asymptotic freedom, the flow of the effective coupling constants away zero. However the present work is progress toward a construction of quantum chromodynamics $(\mathrm{QCD})_{3,4}$, the fundamental theory of the strong interactions. It seems likely that combining Balaban's results on Yang-Mills [5],[6] with the present work would be sufficient, albeit still on a torus.

Acknowledgement: I would like to thank T. Balaban for helpful conversations.

2 Preliminaries

2.1 the model

The basic torus is $\mathbb{T}_M = (\mathbb{R}/L^M\mathbb{Z})^3$ where L is a fixed large positive number and $M \geq 0$ is a fixed nonnegative integer. It has volume L^{3M}. In this torus we consider lattices with spacing L^{-N} defined by

$$\mathbb{T}_M^{-N} = (L^{-N}\mathbb{Z}/L^M\mathbb{Z})^3 \tag{1}$$

Let $\bar{\psi}, \psi$ be fermi fields and let $\mathcal{A}$ be an Abelian gauge field on the lattice. The lattice version of Euclidean $(\mathrm{QED})_3$ in the Feynman gauge is defined by the density

$$\rho(\bar{\psi}, \psi, \mathcal{A}) = \exp\left(-\frac{1}{2}(\mathcal{A}, (-\Delta + \mu^2)\mathcal{A}) - (\bar{\psi}, (D_e(\mathcal{A}) + m)\psi) - \delta v - \delta E\right) \tag{2}$$

Here $D_e(A)$ is the lattice Dirac operator with potential $\mathcal{A}$ and coupling constant $e \geq 0$, and $\delta v, \delta E$ are mass and energy counterterms. We are interested in integrals like the normalization factor (partition function)

$$Z = \int \rho(\bar{\psi}, \psi, \mathcal{A})\ d\bar{\psi}\ d\psi\ d\mathcal{A} \tag{3}$$

and in correlation functions such as the two point function

$$< \psi(x)\bar{\psi}(y) >= Z^{-1} \int \psi(x)\bar{\psi}(y)\ \rho(\bar{\psi}, \psi, \mathcal{A})\ d\bar{\psi}\ d\psi\ d\mathcal{A} \tag{4}$$

The problem is to control the $N \to \infty$ limit.

Let us explain the terms in (2) is more detail. The gauge field $\mathcal{A} = \mathcal{A}(xx')$ is a real valued function on bonds x, x' (nearest neighbors) in $\mathbb{T}_M^{-N}$ satisfying $\mathcal{A}(xx') = -\mathcal{A}(x'x)$.

If $\{e_\mu\} = \{e_1, e_2, e_3\}$ are oriented unit basis vectors we write $\mathcal{A}_\mu(x) = \mathcal{A}(x, x + L^{-N}e_\mu)$. The derivative of $\mathcal{A}_\mu$ in the direction e_ν is

$$(\partial_\nu \mathcal{A}_\mu)(x) = (\mathcal{A}_\mu(x + L^{-N}e_\nu) - \mathcal{A}_\mu(x))/L^{-N} \tag{5}$$

and $(\mathcal{A}, (-\Delta + \mu^2)\mathcal{A})$ is the quadratic form defined by the lattice Laplacian:

$$(\mathcal{A}, (-\Delta + \mu^2)\mathcal{A}) = \sum_{\mu,\nu,x} L^{-3N} |(\partial_\nu \mathcal{A}_\mu)(x)|^2 + \mu^2 \sum_{\mu,x} L^{-3N} |\mathcal{A}_\mu(x)|^2 \tag{6}$$

The fermion fields $\bar{\psi}_\alpha(x), \psi_\alpha(x)$ are indexed by $x \in \mathbb{T}_M^{-N}$ and $1 \leq \alpha \leq 4$. They are the natural basis for the space of functions from the lattice to pairs of four component spinors. They provide a basis for the Grassman algebra generated by this space. This is the space of fermions fields. Integration over fermion fields means projection onto the element of maximal degree. The Dirac operator is given by

$$(\bar{\psi}, D_e(\mathcal{A})\psi) = L^{-2N} \sum_{xx'} \bar{\psi}(x) \gamma_{xx'} e^{ieL^{-N}\mathcal{A}(xx')} \psi(x') \ - \frac{3r}{2} L^{-2N} \sum_x \bar{\psi}(x)\psi(x) \tag{7}$$

If $x' = x \pm L^{-N}e_\mu$ then then $\gamma_{xx'} = \frac{1}{2}(r \pm \gamma_\mu)$ where γ_μ are the usual self-adjoint Dirac matrices satisfying $\{\gamma_\mu, \gamma_\nu\} = 2\delta_{\mu\nu}$. This can also be written as

$$\begin{aligned}(\bar{\psi}, D_e(\mathcal{A})\psi) =& L^{-2N} \sum_{x,\mu} \bar{\psi}(x) (\frac{r + \gamma_\mu}{2}) e^{ieL^{-N}\mathcal{A}(x, x+L^{-N}e_\mu)} \psi(x + L^{-N}e_\mu) \\ &+ L^{-2N} \sum_{x,\mu} \bar{\psi}(x) (\frac{r - \gamma_\mu}{2}) e^{ieL^{-N}\mathcal{A}(x, x-L^{-N}e_\mu)} \psi(x - L^{-N}e_\mu) \\ &- \frac{3r}{2} L^{-2N} \sum_x \bar{\psi}(x)\psi(x)\end{aligned} \tag{8}$$

Formally the r terms disappear as $N \to \infty$ and we get the usual continuum action $\sum_\mu \int \bar{\psi}(x)\gamma_\mu(\partial_\mu + ie\mathcal{A}_\mu(x))\psi(x)dx$. The propagator for this action has some well-known pathologies when $r = 0$, so we take a fixed $0 < r \leq 1$.

Actually we want a modification of the above corresponding to anti-periodic boundary conditions for the fermions. Instead of basis vectors $\bar{\psi}(x), \psi(x)$ indexed by the torus $\mathbb{T}_M^{-N}$ we consider basis vectors $\bar{\psi}(x), \psi(x)$ indexed by the infinite lattice $(L^{-N}\mathbb{Z})^3$, but with the identifications

$$\begin{aligned}\psi(x + L^M e_\mu) &= -\psi(x) \\ \bar{\psi}(x + L^M e_\mu) &= -\bar{\psi}(x)\end{aligned} \tag{9}$$

Then $j(x, x') \equiv \bar{\psi}(x)\gamma_{xx'} e^{ieL^{-N}\mathcal{A}(xx')}\psi(x')$ satisfies $j(x + L^M e_\mu, x' + L^M e_\mu) = j(x, x')$. Thus it is a function on the torus and so we can define sums like $\sum_{xx'} j(x, x')$ which appear in (7). The anti-periodic boundary conditions are necessary for Osterwalder-Schrader positivity, that is for a Hilbert space structure [13]. This is physically desirable and will also be technically useful.

The above expression depends on three parameters: the coupling constant e, the fermion mass m , and the photon mass μ. The parameters e, m are arbitrary. The photon mass is added because the Feynman gauge is not a complete gauge. We need it to suppress constant fields. One would really like to eliminate it, but this would mean picking another gauge or using the Wilson action. In either case the treatment would be more complicated, but still feasible. We regard the photon mass as a convenience, not an essential modification of this UV problem.

The model has a charge conjugation symmetry. Define the charge conjugation matrix C to satisfy $C^T\gamma_\mu C = -\gamma_\mu^T$ and we can take $C^T = C^{-1} = -C$. Then we have $C^T\gamma_{xx'}C = \gamma^T_{x'x}$. Under the transformation

$$\begin{aligned}\bar{\psi} \to & C\psi \\ \psi \to & -C\bar{\psi} \\ \mathcal{A} \to & -\mathcal{A}\end{aligned} \tag{10}$$

the term $(\bar{\psi}, D(\mathcal{A})\psi)$ is invariant. In fact the entire density has this symmetry and we preserve it throughout our analysis.

The term $(\bar{\psi}, D(\mathcal{A})\psi)$ is also invariant under gauge transformations:

$$\begin{aligned}\bar{\psi} \to & e^{ie_0\lambda}\bar{\psi} \\ \psi \to & e^{-ie_0\lambda}\psi \\ \mathcal{A} \to & \mathcal{A} - \partial\lambda\end{aligned} \tag{11}$$

The term $(\mathcal{A}, (-\Delta + \mu^2)\mathcal{A})$ is of course not invariant. Nevertheless we will be able to preserve a substantial amount of gauge invariance throughout the analysis

The scaled model: Before proceeding we scale the problem up to a unit lattice with large volume. This changes our ultraviolet problems to infrared problems and puts us in the natural home for the renormalization group. The new lattice is $\mathbb{T}^0_{N+M}$ with volume $L^{3(N+M)}$ and unit lattice spacing. For fields Ψ, A on this lattice we define $\rho_0(\bar{\Psi}, \Psi, A) = \rho(\bar{\Psi}_{L^{-N}}, \Psi_{L^{-N}}, A_{L^{-N}})$ where

$$\begin{aligned}(A_L)(xx') =& (\sigma_L A)(xx') = L^{-1/2}A(L^{-1}x, L^{-1}x') \\ (\Psi_L)(x) =& (\sigma_L\psi)(x) = L^{-1}\Psi(L^{-1}x)\end{aligned} \tag{12}$$

(The scaling operator σ_L is defined differently for bosons and and fermions). Then

$$\rho_0(\bar{\Psi}, \Psi, \mathcal{A}) = \exp\left(-\frac{1}{2}(A, (-\Delta + \mu_0^2)A) - (\bar{\Psi}, (D_{e_0}(A) + m_0)\Psi) - \delta v_0 - \delta E_0\right) \tag{13}$$

Here the (real) inner products and operators are all on the unit lattice (i.e. put $N = 0$ in (5)-(8)), and the new coupling constants are all very small:

$$e_0 = L^{-N/2}e \qquad m_0 = L^{-N}m \qquad \mu_0 = L^{-N}\mu \tag{14}$$

The mass counterterm is taken to have the Wick-ordered form

$$v_0 = \sum_x :\bar{\Psi}(x)\delta m_0 \Psi(x):_{\hat{S}_0} \equiv \sum_x \bar{\Psi}(x)\delta m_0\Psi(x) - tr(\delta m_0 \hat{S}_0(x,x)) \tag{15}$$

where $\hat{S}_0 = (D(0) + m_0)^{-1}$ and δm_0 is to be specified. In all the above we have used the subscript zero (rather than N) because this is the starting point for the RG flow.

Remark. The Dirac operator $D_{e_0}(A)$ depends on the potential A through the phase $e^{ie_0 A_{xx'}}$. In analyzing the model it is tempting to replace $e^{ie_0A_{xx'}}$ by $1+(e^{ie_0A_{xx'}}-1)$ right from the start. The first term gives a kinetic term and the second a potential. This does break gauge invariance, but the split is natural for a perturbative analysis and the associated RG transformations are clean. We refrain from making the split because we do not have good control over the size of A. The potential is not necessarily small even though e_0 is small. (The term $\exp(-\mu_0^2 \sum A^2)$ in the density does not give any significant suppression of large A because the the coefficient μ_0^2 is too small.) Instead we wait and carry out the split in each fluctuation step. By declining to do it all at once we are going to have background fields in our fermion propagators. This will prove to be a nuisance.

2.2 counterterms

Renormalization means adjusting bare parameters to cancel the singularities in the theory. Since our model is super-renormalizable it suffices to choose the counterterms to cancel singularities in low order perturbation theory. Suppose one splits off a potential as above and computes various quantities to second order in e_0. One finds an apparent logarithmic divergence in the fermion mass and a quadratic divergence in the vacuum energy as $N \to \infty$. (We ignore an apparent linear divergence in the photon mass. This will be ruled out by gauge invariance).

Consider first the fermion mass. In the two point function $< \Psi(x)\bar{\Psi}(y) >$ for the scaled model look at the amputated one-particle irreducible part. The second order contribution is given by certain Gaussian integrals and computing them we find the expression $\delta m_0 \ \delta_{x,y} + \Sigma_0(x,y)$ where

$$\begin{aligned}\Sigma_0(x,y) = &\sum_{x'y'zw} \mathcal{V}^{(1)}_{e_0,\mu}(z,x,x')(D(0)+m_0)^{-1}(x',y')\mathcal{V}^{(1)}_{e_0,\mu}(w,y',y)(-\Delta+\mu_0^2)^{-1}(z,w)\\ &+\sum_{z,z} \mathcal{V}^{(2)}_{e_0,\mu,\mu}(z,z,x,y)(\Delta+\mu_0^2)^{-1}(z,z)\end{aligned} \tag{16}$$

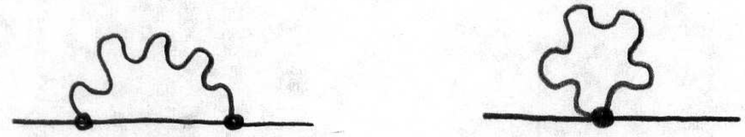

Figure 1: The fermion self-energy $\Sigma_0(x,y)$

Here we have defined vertices

$$\mathcal{V}^{(n)}_{e_0,\mu_1,\dots,\mu_n}(z_1,\cdots z_n,x,x') = [\frac{\partial^n D_{e_0}(A,x,x')}{\partial A_{\mu_1}(z_1)\cdots\partial A_{\mu_n}(z_n)}]_{A=0} = \mathcal{O}(e_0^n) \tag{17}$$

They vanish unless $z_1 = \cdots = z_n$ and $\mu_1 = \cdots = \mu_n$. The vertex $\mathcal{V}^{(1)}_{e_0,\mu}$ is the lattice version of $ie_0\gamma_\mu$. The sums in (16) are restricted to nearest neighbors of x,y in $\mathbb{T}^0_{N+M}$. The expression corresponds to the diagrams shown in figure 1. Terms in which the fermion fields in the potential contract to each other do not occur. [2]

The singularity comes from the non-summability of $\Sigma_0(x,y)$. As $d(x,y)\to\infty$ the best estimates uniform in N are $(-\Delta+\mu_0^2)^{-1}(xx',yy') = \mathcal{O}(d(x,y)^{-1})$ for bosons and $(-D(0)+m_0)^{-1}(x,y) = \mathcal{O}(d(x,y)^{-2})$ for fermions and hence $\Sigma_0(x,y) = \mathcal{O}(d(x,y)^{-3})$. This gives the logarithmic divergence when summed. The counterterm is chosen to compensate and we take

$$\delta m_0 = -\sum_{y\in\mathbb{T}^0_{N+M}} \Sigma_0(x,y) \tag{18}$$

This is independent of x by translation invariance.

When the cutoffs are removed the divergent part of δm_0 formally vanishes by symmetry considerations. This suggests that perhaps we do not really need the mass counterterm. We include it nevertheless as a convenient way to cancel dangerous looking

---

[2] For example such a term is

$$\sum_{\tilde{z}zww'} \mathcal{V}^{(1)}_{e_0,\mu}(\tilde{z},x,y)(-\Delta+\mu_0^2)^{-1}(\tilde{z},z)\ \mathrm{tr}\left(\mathcal{V}^{(1)}_{e_0,\mu}(z,w,w')(D(0)+m_0)^{-1}(w',w)\right)$$

The trace vanishes by charge conjugation invariance for we have that $C^{-1}\mathcal{V}^{(1)}_{e_0,\mu}(z,w,w')C = -[\mathcal{V}^{(1)}_{e_0,\mu}(z,w',w)]^T$ and $C^{-1}(D(0)+m_0)^{-1}(w',w)C = [(D(0)+m_0)^{-1}(w',w)]^T$. Wick ordering removes self-contraction in the counterterm.

terms in our effective actions. Along these lines we mention also that δm_0 is formally a Dirac scalar when the cutoffs are removed. We do not claim it is true as it stands.

The vacuum energy counterterm can also be chosen from looking at the divergences in perturbation theory. But now one would have to include all diagrams up to sixth order. We do not really want to go to the trouble of keeping track of all these diagrams, particularly since the vacuum energy does not contribute at all to the correlation functions. Instead we pick a counterterm by a method more suited to our analysis. The counterterm is taken to have the form

$$\delta E_0 = \sum_{j=0}^{N-1} \delta \mathcal{E}_j \; L^{3(N+M-j)} \tag{19}$$

where the j^{th} term is chosen to remove dangerous terms in the $(j+1)^{st}$ RG step. The factor $L^{3(N+M-j)}$ is the volume in which we will be working at that point. The energy densities $\delta\mathcal{E}_j$ are to be specified, but we will have $\delta\mathcal{E}_j = \mathcal{O}(e_j^2)$ where $e_j = L^{-(N-j)/2}$ is a running coupling constant. Note the quadratic divergence $\delta E_0 = \mathcal{O}(L^{2N})$.

2.3 the RG transformation

The renormalization group (RG) is a series of transformations which average out the short distance features of the model, leaving only the the long distance properties in which we are interested (now that we have scaled the model). Here we define a simple version of the first RG transformation. Our purpose is to explain the general idea and establish some notation. This simple version will not be suitable for iteration which is the eventual goal. *Counterterms are omitted.*

First we define averaging operators. These take functions on $\mathbb{T}^0_{N+M}$ to functions on $\mathbb{T}^1_{N+M}$ and are defined for spinors and vector fields respectively by

$$\begin{aligned} (Q_{e_0}(A)f)(y) &= L^{-3} \sum_{x \in B(y)} \exp\left(ie_0 A(\Gamma_{yx})\right) f(x) \\ (Qh)_\mu(y) &= L^{-3} \sum_{x \in B(y)} h_\mu(x) \end{aligned} \tag{20}$$

Here for $y \in \mathbb{T}^1_{N+M}$ we have defined

$$B(y) = \{x \in \mathbb{T}^0_{N+M} : |x-y| \leq L/2\} \tag{21}$$

The distance is $|x-y| = \sup_\mu |x_\mu - y_\mu|$ so this in an L-cube centered on y. We assume L is odd so the $B(y)$ form a partition. Also Γ_{yx} is a rectilinear path from x to y obtained by successively changing each of the three components, and $A(\Gamma) = \sum_{x'x \in \Gamma} A_{x'x}$. The spinor averaging operator is chosen to be gauge covariant:

$$Q_{e_0}(A - \partial\lambda) = e^{-ie_0\lambda} Q(A) e^{ie_0\lambda} \tag{22}$$

Let $Q_{e_0}(A)^T, Q^T$ denote the transpose operators which take functions on $\mathbb{T}^1_{N+M}$ to functions on $\mathbb{T}^0_{N+M}$. These are defined with respect to the natural inner product on $\mathbb{T}^1_{N+M}$, i.e. sums are weighted by L^3. They are computed to be

$$\begin{aligned} (Q_{e_0}(A)^T f)(x) &= \exp\left(ie_0 A(\Gamma_{yx})\right) f(y) \\ (Q^T h)_\mu(x) &= h_\mu(y) \end{aligned} \tag{23}$$

where y is the unique point so $x \in B(y)$. We have $Q_{e_0}(-A)Q_{e_0}(A)^T = I$ and $QQ^T = I$ while $Q_{e_0}(-A)^T Q_{e_0}(A)$ and Q^TQ are projection operators.

Now starting with the density ρ_0 on $\mathbb{T}^0_{N+M}$ then we define a transformed density on $\mathbb{T}^1_{N+M}$ by [3]

$$\begin{aligned} \tilde{\rho}_1(\Psi, A) =& c_0 \int \exp\left(-\frac{a}{2L^2}|A - QA_0|^2\right) \exp\left(-\frac{a}{L}|\Psi - Q_{e_0}(A_0)\Psi_0|^2\right) \\ & \rho_0(\Psi_0, A_0)\ d\Psi_0\ dA_0 \end{aligned} \tag{24}$$

We have passed to a larger Grassman algebra generated by Ψ, Ψ_0 and are now integrating over the Ψ_0 part of it. We have also introduced the (somewhat abusive) notation

$$|\Psi - Q(A_0)\Psi_0|^2 = (\bar{\Psi} - Q_{e_0}(-A_0)\bar{\Psi}_0, \Psi - Q_{e_0}(A_0)\Psi_0) \tag{25}$$

The positive constant a is arbitrary and the constant c_0 is chosen so that

$$\int \tilde{\rho}_1(\Psi, A)\ d\Psi\ dA = \int \rho_0(\Psi_0, A_0)\ d\Psi_0\ dA_0 \tag{26}$$

Now insert the expression for ρ_0 into (24). The quadratic form in (A, A_0) is

$$\frac{a}{2L^2}|A - QA_0|^2 + \frac{1}{2}(A_0, (-\Delta + \mu_0^2)A_0) \tag{27}$$

and we would like to diagonalize it. To this end we introduce

$$\Delta^{\#} \equiv -\Delta + \mu_0^2 + \frac{a}{L^2}\ Q^TQ \tag{28}$$

This is positive and so we can also define

$$\begin{aligned} C =& (\Delta^{\#})^{-1} \\ H_1 =& \frac{a}{L^2}\ (\Delta^{\#})^{-1}Q^T \\ \tilde{\Delta}_1 =& \frac{a}{L^2} - \frac{a^2}{L^4}\ Q(\Delta^{\#})^{-1}Q^T \end{aligned} \tag{29}$$

---

[3] We frequently allow Ψ to stand for the pair $(\bar{\Psi}, \Psi)$.

Here C is an operator on $\mathbb{T}^0_{N+M}$ (more precisely an operator on functions on bonds in $\mathbb{T}^0_{N+M}$), H_1 is an operator from $\mathbb{T}^1_{N+M}$ to $\mathbb{T}^0_{N+M}$, and $\tilde{\Delta}_1$ is an operator on $\mathbb{T}^1_{N+M}$. The quadratic form is diagonalized by the change of variables $A_0 \to A_0 + H_1 A$. Under this transformation the quadratic form becomes

$$\frac{1}{2}(A, \tilde{\Delta}_1 A) + \frac{1}{2}(A_0, \Delta^{\#} A_0) \tag{30}$$

We have split it into a piece for the background field A, and a piece for the fluctuation field A_0. Now identify the Gaussian measure

$$d\mu_{C_0}(A_0) = Z_1^{-1} \exp\left(-\frac{1}{2}(A_0, \Delta^{\#} A_0)\right) dA_0 \tag{31}$$

where Z_1 is a normalization factor. Defining $\tilde{A} = H_1 A$, and omitting counterterms for simplicity our transformed density has become

$$\begin{aligned}&\tilde{\rho}_1(\Psi, A) = c_0 \exp\left(-\frac{1}{2}(A, \tilde{\Delta}_1 A)\right)\ Z_1 \\ &\int \exp\Big(-\frac{a}{L}|\Psi - Q_{e_0}(\tilde{A} + A_0)\Psi_0)|^2 - (\bar{\Psi}_0, (D_{e_0}(\tilde{A} + A_0) + m_0)\Psi_0)\Big)\, d\Psi_0\ d\mu_{C_0}(A_0)\end{aligned} \tag{32}$$

Next we define a potential V_0 by

$$\begin{aligned}&\frac{a}{L}|\Psi - Q_{e_0}(\tilde{A} + A_0)\Psi_0|^2 + (\bar{\Psi}_0, (D_{e_0}(\tilde{A} + A_0) + m_0)\Psi_0) \\ =&\frac{a}{L}|\Psi - Q_{e_0}(\tilde{A})\Psi_0)|^2 + (\bar{\Psi}_0, (D_{e_0}(\tilde{A}) + m_0)\Psi_0) + V_0(\Psi, \Psi_0, \tilde{A}, A_0)\end{aligned} \tag{33}$$

Thus V_0 is the part of the fermion quadratic form depending on the fluctuation field A_0. The fluctuation field is massive due to the $Q^T Q$ in $\Delta^{\#}$. Hence large A_0 is suppressed and we can expect that V_0 is small. The most important contribution to V_0 is from the term

$$(\bar{\Psi}_0, D_{e_0}(\tilde{A} + A_0)\Psi_0) - (\bar{\Psi}_0, D_{e_0}(\tilde{A})\Psi_0) = \sum_{xx'} \bar{\Psi}_0(x)\gamma_{xx'} e^{ie_0 \tilde{A}(xx')}(e^{ie_0 A_0(xx')} - 1)\Psi_0(x') \tag{34}$$

The lowest order term in e_0 gives the classical interaction vertex, but with the background $e^{ie_0\tilde{A}}$. Higher order terms give multiphoton vertices. There are also vertices coming from the Q terms.

Now consider the fermion quadratic form with background field, i.e. the first two terms on the right side of (33). We want to diagonalize in Ψ, Ψ_0. This involves the inverse of the operator

$$D^{\#}(\tilde{A}) \equiv D_{e_0}(\tilde{A}) + m_0 + \frac{a}{L}\ Q_{e_0}(-\tilde{A})^T Q_{e_0}(\tilde{A}) \tag{35}$$

(We could write $Q_{e_0}(-\tilde{A})^T$ as $Q_{e_0}(\tilde{A})^*$ where the adjoint refers to a complex inner product). However we cannot control the inverse unless with have control over the field strength for $\tilde{A}$. This is an issue we address in the the rest of the paper. *For now we just assume that* $e_0|\partial\tilde{A}|$ *is sufficiently small.* In this case we can define

$$\begin{aligned}
\Gamma(\tilde{A}) =& D^{\#}(\tilde{A})^{-1} \\
H_1(\tilde{A}) =& \begin{cases} \frac{a}{L}\ D^{\#}(\tilde{A})^{-1} Q_{e_0}(-\tilde{A})^T & \text{on } \Psi \\ \frac{a}{L}\ [D^{\#}(\tilde{A})^{-1}]^T Q_{e_0}(\tilde{A})^T & \text{on } \bar{\Psi} \end{cases} \\
\tilde{D}_1(\tilde{A}) =& \frac{a}{L} - \frac{a^2}{L^2}\ Q_{e_0}(\tilde{A}) D^{\#}(\tilde{A})^{-1} Q_{e_0}(-\tilde{A})^T
\end{aligned} \tag{36}$$

Now make the change of variables $\Psi_0 \to \Psi_0 + H_1(\tilde{A})\Psi$ and $\bar{\Psi}_0 \to \bar{\Psi}_0 + H_1(\tilde{A})\bar{\Psi}$. The quadratic form becomes

$$(\bar{\Psi}, \tilde{D}_1(\tilde{A})\Psi) + (\bar{\Psi}_0, D^{\#}(\tilde{A})\Psi_0) \tag{37}$$

We identify the fermion Gaussian measure

$$d\mu_{\Gamma(\tilde{A})}(\Psi_0) = \tilde{Z}_1(\tilde{A})^{-1} \exp\Big(-(\bar{\Psi}_0, D^{\#}(\tilde{A})\Psi_0)\Big)\, d\Psi_0 \tag{38}$$

where $\tilde{Z}_1(\tilde{A})$ is the normalization factor. With $\tilde{\Psi}(\tilde{A}) = H_1(\tilde{A})\Psi$ the complete fluctuation integral is now the Gaussian integral

$$\tilde{\Xi}_1(\Psi, \tilde{A}) \equiv \int \exp\Big(-V_0(\Psi, \Psi_0 + \tilde{\Psi}(\tilde{A}), \tilde{A}, A_0)\Big)\, d\mu_{\Gamma(\tilde{A})}(\Psi_0) d\mu_C(A_0) \tag{39}$$

and the overall density is

$$\tilde{\rho}_1(\Psi, A) = c_0 \exp\left(-\frac{1}{2}(A, \tilde{\Delta}_1 A)) - (\bar{\Psi}, \tilde{D}_1(\tilde{A})\Psi)\right) Z_1 \tilde{Z}_1(\tilde{A})\ \tilde{\Xi}_1(\Psi, \tilde{A}) \tag{40}$$

We note that $(\bar{\Psi}, \tilde{D}_1(\tilde{A})\Psi)$ and $\tilde{Z}_1(\tilde{A})$ and $\tilde{\Xi}_1(\Psi, \tilde{A})$ are all invariant under gauge transformations in the variables $(\bar{\Psi}, \Psi, \tilde{A})$. (They would not be invariant in the fundamental variables $(\bar{\Psi}, \Psi, A)$.)

Finally we scale back to fields on a unit lattice. For Ψ_1, A_1 on $\mathbb{T}^0_{N+M-1}$ by we define

$$\rho_1(\Psi_1, A_1) = \tilde{\rho}_1(\Psi_{1,L}, A_{1,L}) \tag{41}$$

For the boson parts of this we define $\mathcal{Q} = \sigma_L^{-1} Q \sigma_L$ which is the natural averaging operator mapping functions on $\mathbb{T}^{-1}_{N+M-1}$ (an L^{-1} lattice) to functions on $\mathbb{T}^0_{N+M-1}$. Then we define

$$\begin{aligned}
G_1 =& L^{-2}\sigma_L^{-1} C_0\ \sigma_L = \left(-\Delta + \mu_1^2 + \mathcal{Q}^T\mathcal{Q}\right)^{-1} \\
\mathcal{H}_1 =& \sigma_L^{-1} H_1 \sigma_L = a\ G_1 \mathcal{Q}^T \\
\Delta_1 =& L^2 \sigma_L^{-1} \tilde{\Delta}_1 \sigma_L = aI - a^2 \mathcal{Q} G_1 \mathcal{Q}^T
\end{aligned} \tag{42}$$

Here G_1 is on operator on on $\mathbb{T}^{-1}_{N+M-1}$, $\mathcal{H}_1$ is an operator from $\mathbb{T}^{0}_{N+M-1}$ to $\mathbb{T}^{-1}_{N+M-1}$, and Δ_1 is an operator on $\mathbb{T}^{0}_{N+M-1}$. The background field $\tilde{A} = H_1 A$ scales to $H_1 A_{1,L}$ on $\mathbb{T}^{0}_{N+M}$, and it can now be written $\mathcal{A}_{1,L}$ where $\mathcal{A}_1 = \mathcal{H}_1 A_1$ is a field on $\mathbb{T}^{-1}_{N+M-1}$

Now for fermions we define $\mathcal{Q}_{e_1}(\mathcal{A}_1) = \sigma_L^{-1} Q_{e_0}(\mathcal{A}_{1,L})\sigma_L$ which is the natural averaging operator on $\mathbb{T}^{-1}_{N+M-1}$ with $e_1, \mathcal{A}_1$. Then we define

$$\begin{aligned} S_1(\mathcal{A}_1) =& L^{-1}\sigma_L^{-1}\Gamma_0(\mathcal{A}_{1,L})\ \sigma_L = \left(D_{e_1}(\mathcal{A}_1) + m_1 + \mathcal{Q}_{e_1}(-\mathcal{A}_1)^T \mathcal{Q}_{e_1}(\mathcal{A}_1)\right)^{-1} \\ \mathcal{H}_1(\mathcal{A}_1) =& \sigma_L^{-1} H_1(\mathcal{A}_{1,L})\sigma_L = \begin{cases} aS_1(\mathcal{A}_1)\mathcal{Q}_{e_1}(-\mathcal{A}_1)^T & \text{on } \Psi \\ aS_1(\mathcal{A}_1)^T \mathcal{Q}_{e_1}(\mathcal{A}_1)^T & \text{on } \bar{\Psi} \end{cases} \\ D_1(\mathcal{A}_1) =& L\ \sigma_L^{-1}\tilde{D}_1(\mathcal{A}_{1,L})\sigma_L = aI - a^2 \mathcal{Q}_{e_1}(\mathcal{A}_1) S_1(\mathcal{A}_1) \mathcal{Q}_{e_1}(-\mathcal{A}_1)^T \end{aligned} \tag{43}$$

The fermi field $\tilde{\Psi}(\tilde{A})$ scales to $H_1(\mathcal{A}_{1,L})\Psi_{1,L}$ which can be written $(\psi_1(\mathcal{A}_1))_L$ where $\psi_1(\mathcal{A}_1) \equiv \mathcal{H}_1(\mathcal{A}_1)\Psi_1$. This field appears in the scaled fluctuation integral

$$\Xi_1(\Psi_1, \mathcal{A}_1) = \tilde{\Xi}_1(\Psi_{1,L}, \mathcal{A}_{1,L}) \tag{44}$$

We also define $Z_1(\mathcal{A}_1) = \tilde{Z}_1(\mathcal{A}_{1,L})$. Then we have for the new density (still under a small field assumption)

$$\rho_1(\Psi_1, A_1) = c_0 \exp\left(-\frac{1}{2}(A_1, \Delta_1 A_1)) - (\bar{\Psi}_1, D_1(\mathcal{A}_1)\Psi_1)\right) Z_1 Z_1(\mathcal{A}_1)\Xi_1(\Psi_1, \mathcal{A}_1) \tag{45}$$

This expression shows a nice split into a kinetic part (the exponential) and an effective interaction (the rest). Next one could compute the leading contributions to $Z_1(\mathcal{A}_1)$ and $\Xi_1(\Psi_1, \mathcal{A}_1)$ in perturbation theory. However we leave this for the full treatment.

Another representation: Suppose we undo some of the steps that got us here. Go back to the expression (40) for $\tilde{\rho}_1(\Psi, A)$. Express $\tilde{Z}_1(\tilde{A})$ and Z_1 as integrals over Ψ_0 and A_0 and then make the inverse transformations $\Psi_0 \to \Psi_0 - \tilde{\Psi}(\tilde{A})$ and $A_0 \to A_0 - \tilde{A}$. This yields

$$\begin{aligned} \tilde{\rho}_1(\Psi, A) =& c_0\ \tilde{\Xi}_1(\Psi, \tilde{A}) \int \exp\left(-\frac{a}{2L^2}|A - QA_0|^2\right) \exp\left(-\frac{a}{L}|\Psi - Q(\tilde{A})\Psi_0|^2\right) \\ & \exp\left(-\frac{1}{2}(A_0, (-\Delta + \mu_0^2)A_0) - (\bar{\Psi}_0, (D_{e_0}(\tilde{A}) + m_0)\Psi_0)\right) d\Psi_0\ dA_0 \end{aligned} \tag{46}$$

This can also be scaled to get another representation for $\rho_1(\Psi_1, A_1)$. The expression (46) is close to what we started with in (24). The change is that the gauge field A_0 has been replaced with a background field $\tilde{A}$ with fewer degrees of freedom, and there is a corresponding correction factor $\tilde{\Xi}_1(\Psi, \tilde{A})$. Variations of this representation will be useful for iteration.

2.4 some tools

We introduce some tools that we need for subsequent developments. These are roughly ordered by length scale.

A. We use random walk expansions for the basic propagators C and $\Gamma(A)$ assuming $e_0|\partial A|$ is sufficiently small. These are developed on a scale M_0 which is a fixed power of L. We consider the M_0 lattice $\mathbb{T}^{M_0}_{N+M}$ A path is a sequence $\omega = (j_0, j_1, \dots, j_n)$ of points in this lattice which are neighbors in the sense that $|j_\alpha - j_{\alpha+1}| = 0$ or M_0. Associated with a path ω is a sequence $(\mathcal{O}_{j_0}, \mathcal{O}_{j_1}, \cdots, \mathcal{O}_{j_n})$ of *overlapping* $2M_0$ cubes $\mathcal{O}_j$ centered on the points j. We write $\omega : x \to y$ if $x \in \mathcal{O}_{j_0}$ and $y \in \mathcal{O}_{j_n}$.

The random walk expansion has the form

$$\begin{aligned} \Gamma(A,x,y) &= \sum_{\omega : x \to y} \Gamma_\omega(A,x,y) \\ C(x,y) &= \sum_{\omega : x \to y} C_\omega(x,y) \end{aligned} \tag{47}$$

The individual terms are $(\mathcal{O}(1)M_0^{-1})^{\ell(\omega)}$ where $\ell(\omega)$=number of steps in ω, and this is sufficient for convergence if M_0 is large enough. From the condition $\omega : x \to y$ we can also extract some exponential decay and obtain for $\beta = \mathcal{O}(M_0^{-1})$

$$|\Gamma(A,x,y)|, \quad |C(x,y)| \leq C \exp(-\beta d(x,y)) \tag{48}$$

We also note that $\Gamma_{\Lambda,\omega}(A)$ depends on A only in $\mathcal{O}_{j_0} \cup \mathcal{O}_{j_1} \cup \cdots \cup \mathcal{O}_{j_n}$.

See appendix A for details of this construction and the original references.

B. The fluctuation integrals will be processed by a cluster expansion. This means all terms must be localized. This will be done on a scale M_1, also a fixed power of L but larger than M_0. Δ will denote a M_1 cube centered on the $\mathbb{T}^{M_1}_{N+M}$ lattice. These partition the lattice. A union of such Δ will be denoted by $X, Y, Z, \dots$. Such a set is connected and called a polymer if for any two $\Delta, \Delta' \subset X$ there is a sequence $\Delta, \Delta_1, \dots \Delta_n, \Delta'$ in X such that consecutive blocks touch in any dimension. The terms in our effective potentials will be polymer sums $\sum_X E(X)$ where $E(X)$ only depends on fields in X.

C. We introduce a scale beyond which correlations are completely negligible. This is defined by

$$r(e_0) = (\log e_0^{-1})^r = \left(\frac{N}{2} + \log e^{-1}\right)^r \tag{49}$$

for some small positive integer r. If N is large then e_0 is small and $r(e_0)$ is large; we assume it is larger than M_1. Let $R_0 = \inf_m\{L^m : L^m \geq r(e_0)\}$ be an associated power of L. We will consider blocks $\Box$ of size R_0 centered on points in $\mathbb{T}^{R_0}_{N+M}$ and collections of such blocks denoted $\Omega, \Lambda, \dots$.

We also will use approximate propagators which do not couple beyond this scale. These are defined in terms of the random walk expansion. Let $\chi_\omega(x,y)$ is the characteristic function of paths which stay within $r(e_0)/2$ of both x and y. Then we define

$$\begin{aligned} C^{loc}(x,y) &= \sum_{\omega : x \to y} C_\omega(x,y)\chi_\omega(x,y) \\ \Gamma^{loc}(A,x,y) &= \sum_{\omega : x \to y} \Gamma_\omega(A,x,y)\chi_\omega(x,y) \end{aligned} \tag{50}$$

These vanish for $d(x,y) \geq r(e_0)/2$ and still satisfy (48).

D. We introduce a scale which distinguishes between large and small values of $|\partial A|$. This is defined by

$$p(e_0) = (\log e_0^{-1})^p = \left(\frac{N}{2} + \log e^{-1}\right)^p \tag{51}$$

for some integer p larger than r. "Small fields" will satisfy conditions like $|\partial A| \leq \mathcal{O}(p(e_0))$ and may actually be rather large. Still $e_0|\partial A|$ would be small as required for the existence of $\Gamma(A)$.

F. Finally we discuss introduce some norms for fermions. Let ξ stand for $(0,\alpha,x)$ or $(1,\alpha,x)$ with $x \in \mathbb{T}^0_{N+M}$ and $1 \leq \alpha \leq 4$. Then define $\Psi(0,\alpha,x) = \Psi_\alpha(x)$ and $\Psi(1,\alpha,x) = \bar{\Psi}_\alpha(x)$. We consider elements of the Grassmann algebra of the form:

$$K(\Psi) = \sum_{n=0}^{\infty} 1/n! \sum_{\xi_1,\dots,\xi_n} k_n(\xi_1,\dots,\xi_n)\Psi(\xi_1)\dots\Psi(\xi_n) \tag{52}$$

The kernel k_n may also depend on the gauge field A. A family of norms is defined by

$$\|K\|_h = \sum_{n=0}^{\infty} \frac{h^n}{n!}\|k_n\|_1 \tag{53}$$

where $\|k_n\|_1$ is the ℓ_1 norm and $h = \mathcal{O}(1)$ is an adjustable parameter. These norms satisfy $\|KL\|_h \leq \|K\|_h\|L\|_h$. Properties and variations are discussed in appendix B.

We will also want to consider functions which only depend on dressed fields like $\tilde{\Psi} = \tilde{\Psi}(\tilde{A}) = H_1(\tilde{A})\Psi$. These would have the form

$$K(\tilde{\Psi}) = \sum_{n=0}^{\infty} 1/n! \sum_{\xi_1,\dots,\xi_n} k_n(\xi_1,\dots,\xi_n)\tilde{\Psi}(\xi_1)\dots\tilde{\Psi}(\xi_n) \tag{54}$$

We define a *kernel norm* by

$$|K|_h = \sum_{n=0}^{\infty} \frac{h^n}{n!}\|k_n\|_1 \tag{55}$$

This still satisfies $|KL|_h \leq |K|_h|L|_h$.

3 The first step

We now give another version of the first RG transformation and this time it is something we can iterate. The idea is to break up the RG integral over the gauge field into a large fields and small fields. This is done at each point in space time we generate a sum over regions where the field is large and regions where the field is small. In the small field region we can carry out the analysis of effective action that we have sketched. Furthermore we can make a perturbation expansion with good control over the remainder. The contribution of the large field region makes a tiny contribution due to tiny factors from the free action. These small factors are enough to control the sum over the regions. We now enter into the details which follow especially [2], [8].

3.1 the split

We analyze (24), but now splitting into large and small field regions. The small field region will be a set on which the following inequalities hold

$$\begin{aligned} |\partial A_0| \leq & \ p(e_0) \\ |A_0| \leq & \ \mu_0^{-1} p(e_0) \\ |A - QA_0| \leq & \ p(e_0) \end{aligned} \tag{56}$$

These correspond to various terms in the action. Fields which violate them will be exponentially suppressed.

Specifically we insert under the integral sign the expression

$$1 = \sum_{\Omega} \zeta_0(\Omega^c, A, A_0)\chi_0(\Omega, A, A_0) \tag{57}$$

Here Ω is an arbitrary collection of blocks $\square$ of size R_0. The function $\chi_0(\Omega, A, A_0)$ enforces the inequalities (56) on Ω and we take it to have the form

$$\begin{aligned} &\chi_0(\Omega, A, A_0) \\ &= \prod_{x\in\Omega} \chi(|\partial A_0(x)|/p(e_0)) \prod_{x\in\Omega} \chi(|A_0(x)|/\mu_0^{-1}p(e_0)) \prod_{y\in\Omega} \chi(|(A - QA_0)(y)|/p(e_0)) \end{aligned} \tag{58}$$

where $\chi(\alpha)$ is a smooth positive function interpolating between $\chi = 1$ for $|\alpha| \leq \frac{1}{2}$ and $\chi = 0$ for $|\alpha| \geq 1$. We assume the derivatives satisfy $|\chi^{(n)}| \leq \mathcal{O}(n!^2)$. The function $\zeta_0(\Omega^c, A, A_0)$ is also smooth and enforces that at least one of the inequalities (56) (with a factor $\frac{1}{2}$) is violated at some point in every block in Ω^c. For the explicit formula see [2], [8].

Now we have

$$\begin{aligned} \tilde{\rho}_1(\Psi, A) = & c_0 e^{\delta E_0} \sum_{\Omega} \int d\Psi_0 dA_0 \ \zeta_0(\Omega^c, A, A_0) \ \chi_0(\Omega, A, A_0) \\ & \exp\left(-\frac{a}{2L^2}|A - QA_0|^2 - \frac{1}{2}(A_0, (-\Delta + \mu_0^2)A_0) \right) \\ & \exp\left(-\frac{a}{L}|\Psi - Q_{e_0}(A_0)\Psi_0|^2 + (\bar{\Psi}_0, (D_{e_0}(A_0) + m_0)\Psi_0) - v(\delta m_0) \right) \end{aligned} \tag{59}$$

3.2 boson translation

Again we seek to diagonalize the boson quadratic form, but now only in the small field region. We define a local version of H_1 by

$$H_1^{loc} = \frac{a}{L^2} C^{loc} Q^T \tag{60}$$

We approximately diagonalize by making the transformation

$$A_0 \rightarrow A_0 + [H_1^{loc} A]_{\Omega'} \equiv A_0 + \tilde{A}_{\Omega'} \tag{61}$$

Here Ω' is Ω shrunk by a corridor of R_0 blocks so that $d(\Omega^c, \Omega') = R_0 \geq r(e_0)$. Since H_1^{loc} has range $r(e_0)/2$ the expression $[H_1^{loc} A]_{\Omega'}$ only depends on A in Ω where we have some control.

Lemma 1 *Under the transformation (61) the boson quadratic form (27) becomes*

$$\frac{1}{2}(A, [\tilde{\Delta}_1]_{\Omega} A) + \frac{1}{2}(A_0, \Delta^{\#} A_0) + F^b + W^b \tag{62}$$

Here each $F^b = F^b(A, A_0)$ is localized in $(\Omega'')^c$ and $W^b = W^b(A, A_0)$ has the form $W^b = \sum_{X \subset \Omega} W^b(X)$ where the sum is over polymers X. The function $W^b(X) = W^b(X, A, A_0)$ only depends on A, A_0 in X. Assuming the bounds (56) we have with $\beta = M_0^{-1}$

$$|W^b(X, A, A_0)| \leq \mathcal{O}(1) e^{-\frac{1}{2}\beta r(e_0)} e^{-\frac{1}{2}\beta M_1 |X|_1} \tag{63}$$

Remarks. Here are some notational conventions

1. If f is a function then $f_\Omega = \chi_\Omega f$ is the restriction to Ω. If T is an operator the $T_\Omega = \chi_\Omega T \chi_\Omega$ and $T_{\Omega\Omega'} = \chi_\Omega T \chi_{\Omega'}$.
2. The general convention is that constants denoted $\mathcal{O}(1)$ may depend on the parameters L, M_0, M_1, μ, but not on e, m or on the fundamental cutoffs N, M. A constant which is independent of all parameters is designated as universal.

3. The symbol $|X|_1$ stands for the number of elementary M_1 blocks in X. Thus the volume is $|X| = M_1^3 |X|_1$. The quantity $M_1|X|_1$ is the linear size of $|X|$. In fact if $\mathcal{L}(X)$ is the length of the shortest tree joining the centers of the blocks in X then $\mathcal{L}(X) = M_1(|X|_1 - 1)$. We could have written the bound with $\mathcal{L}(X)$. Since $\beta M_1 = \mathcal{O}(M_0^{-1}M_1)$ is assumed large the factor $e^{-\frac{1}{2}\beta M_1|X|_1}$ controls the sum over X. The relevant standard bound is that for κ large enough

$$\sum_{X \supset \Delta} e^{-\kappa|X|_1} \leq 1 \tag{64}$$

Or we could replace the condition $X \supset \Delta$ by X touches Δ.

4. Note that $e^{-r(e_0)} = \mathcal{O}(e_0^n)$ for any n; it is extremely small.

Proof. Making the translation the term quadratic in A_0 remains $\frac{1}{2}(A_0, \Delta^{\#}A_0)$ where $\Delta^{\#}$ is defined in (28).

The cross term is

$$(A_0, \Delta^{\#}[H_1^{loc}A]_{\Omega'}) - \frac{a}{L^2}(QA_0, A) \tag{65}$$

We replace A_0 by $A_{0,\Omega}$. In the first term there is no change and the difference for the second term is localized in Ω^c and contributes to F^b. Thus it suffices to consider (65) with $A_{0,\Omega}$. Next we write

$$[H_1^{loc}A]_{\Omega'} = [H_1^{loc}A_\Omega]_{\Omega'} = H_1^{loc}A_\Omega - [H_1^{loc}A_\Omega]_{(\Omega')^c} \tag{66}$$

The term $[H_1^{loc}A_\Omega]_{(\Omega')^c}$ has A dependence in $\Omega \cap (\Omega'')^c$, and its contribution also has A_0 dependence in this set. Thus these terms contribute to F^b. We are left with

$$(A_{0,\Omega}, \Delta^{\#}H_1^{loc}A_\Omega) - \frac{a}{L^2}(QA_{0,\Omega}, A_\Omega) \tag{67}$$

If we replace H_1^{loc} by H_1 we get zero. Thus we can write this term as

$$W_1 \equiv (A_{0,\Omega}, \Delta^{\#}(H_1^{loc} - H_1)A_\Omega) \tag{68}$$

The terms quadratic in A have the form

$$\frac{a}{2L^2}(A, A) - \frac{a}{L^2}(A, Q[H_1^{loc}A]_{\Omega'}) + \frac{1}{2}([H_1^{loc}A]_{\Omega'}, \Delta^{\#}[H_1^{loc}A]_{\Omega'}) \tag{69}$$

We replace A by A_Ω. The difference only comes from the first term and it contributes to F^b. We also insert (66) and again the terms arising from $[H_1^{loc}A_\Omega]_{(\Omega')^c}$ are all localized in $\Omega \cap (\Omega'')^c$ and contribute to F_b. We are left with

$$\frac{a}{2L^2}(A_\Omega, A_\Omega) - \frac{a}{L^2}(A_\Omega, QH_1^{loc}A_\Omega) + \frac{1}{2}(H_1^{loc}A_\Omega, \Delta^{\#}H_1^{loc}A_\Omega) \tag{70}$$

If we replace H_1^{loc} by H_1 we get $\frac{1}{2}(A_\Omega, \tilde{\Delta}_1 A_\Omega) = \frac{1}{2}(A, \tilde{\Delta}_{1,\Omega} A)$. The difference is

$$\begin{aligned} W_2 \equiv & -\frac{a}{L^2}(A_\Omega, Q(H_1^{loc} - H_1)A_\Omega) \\ & + \frac{1}{2}((H_1^{loc} - H_1)A_\Omega, \Delta^\# H_1^{loc} A_\Omega) + \frac{1}{2}(H_1 A_\Omega, \Delta^\# (H_1^{loc} - H_1)A_\Omega) \end{aligned} \tag{71}$$

Now we have established the representation (62) with $W^b = W_1 + W_2$.

Let us analyze W_1. It can be written

$$W_1 = (A_0, w_1 A) = \sum_{x,y \in \Omega} A_{\mu,0}(x) w_{1,\mu,\nu}(x,y) A_\nu(y) \tag{72}$$

Now w_1 depends on $H_1 - H_1^{loc}$ and hence on $C - C^{loc}$. In appendix A, lemma 17, we use a random walk expansion to find a local expansion $C - C^{loc} = \sum_X \delta C(X)$ in which $\delta C_{\mu,\nu}(X, x, y)$ is supported on $X \times X$ and only very large X contribute. This leads to an expansion $w_1 = \sum_X w_1(X)$ with $w_{1,\mu,\nu}(X, x, y)$ supported on $X \times X$ and satisfying

$$|w_1(X, x, y)| \leq \mathcal{O}(1) e^{-\beta r(e_0)} e^{-\beta M_1 |X|_1} e^{-\beta d(x,y)} \tag{73}$$

Now we have $W_1 = \sum_X W_1(X)$ where $W_1(X) = (A_0, w_1(X)A)$. We have the weak bounds $|A_0| \leq \mu_0^{-1} p(e_0)$ and

$$|A| \leq |A - QA_0| + |QA_0| \leq \mathcal{O}(\mu_0^{-1} p(e_0)) \tag{74}$$

The factors $\mathcal{O}(\mu_0^{-1} p(e_0))$ are compensated by a factor $e^{-\frac{1}{2}\beta r(e_0)}$. We also get a volume factor $|X| = M_1^3 |X|_1$ which is dominated by a factor $e^{-\frac{1}{2}\beta M_1 |X|_1}$. Overall we have

$$|W_1(X)| \leq e^{-\frac{1}{2}\beta r(e_0)} e^{-\frac{1}{2}\beta M_1 |X|_1} \tag{75}$$

The analysis of W_2 is similar. This completes the proof.

At this point we have

$$\begin{aligned} & \tilde{\rho}_1(\Psi, A) = c_0 e^{\delta E_0} \sum_\Omega \int d\Psi_0 dA_0 \ \zeta_0(\Omega^c, A, A_0) \ \chi_0(\Omega, A, \tilde{A}_{\Omega'} + A_0) \\ & \exp\left(-\frac{1}{2}(A, \tilde{\Delta}_{1,\Omega} A) - \frac{1}{2}(A_0, \Delta^\# A_0) - F^b - W^b\right) \\ & \exp\left(-\frac{a}{L}|\Psi - Q_{e_0}(\tilde{A}_{\Omega'} + A_0)\Psi_0|^2 - (\bar{\Psi}_0, (D_{e_0}(\tilde{A}_{\Omega'} + A_0) + m_0)\Psi_0) - v(\delta m_0)\right) \end{aligned} \tag{76}$$

3.3 new field restrictions

Let us consider the characteristic function $\chi_0(\Omega, A, \tilde{A}_{\Omega'} + A_0)$ where we recall that A is a function on $\mathbb{T}^1_{N+M}$ and that $A_0, \tilde{A} = H_1^{loc} A$ are functions on $\mathbb{T}^0_{N+M}$. The characteristic function imposes that on Ω'

$$\begin{aligned} |\partial(\tilde{A} + A_0)| \leq & \ p(e_0) \\ |\tilde{A} + A_0| \leq & \ \mu_0^{-1} p(e_0) \\ |A - Q(\tilde{A} + A_0)| \leq & \ p(e_0) \end{aligned} \tag{77}$$

These inequalities imply inequalities on the fields $A, A_0, \tilde{A}$ separately as follows

Lemma 2 *Assume, (77) holds on Ω'. Then there are constants C_1, C_2 such that*

1. $|\partial A| \leq C_1 p(e_0)$ *and* $|A| \leq C_1 \mu_0^{-1} p(e_0)$ *on* Ω'.
2. $\tilde{A} = Q^T A + \mathcal{O}(p(e_0))$ *on* Ω''
3. $|A_0| \leq \quad C_1 p(e_0)$ *on* Ω''
4. $|\partial \tilde{A}| \leq C_2 p(e_0)$ *and* $|\tilde{A}| \leq C_2 \mu_0^{-1} p(e_0)$ *on* Ω''

Remarks. The bound $\mathcal{O}(p(e_0))$ on the fluctuation field A_0 is a substantial improvement over $\mathcal{O}(\mu_0^{-1} p(e_0))$. Since we are on a unit lattice we have the same bound for ∂A_0.

The last bound follows directly from (1.) and (3.), a fact we use later on.

Proof. The proof follows [2].

1. Let $\check{A} = \tilde{A} + A_0$. We have for $y, y + Le_\mu \in \Omega'$

$$\begin{aligned} |(\partial_\mu A_\nu)(y)| =& L|A_\nu(y) - A_\nu(y + Le_\mu)| \\ \leq& L|(Q\check{A}_\nu)(y) - (Q\check{A}_\nu)(y + Le_\mu)| + \mathcal{O}(p(e_0)) \\ \leq& \mathcal{O}(p(e_0)) \end{aligned} \tag{78}$$

   where we have used the first and third bounds in (77) . This proves the bound on ∂A. The bound on $|A|$ follows similarly from second and third bounds in (77).

2. If $x \in B(y)$ then $(Q^T A)(x) = A(y)$. Thus we must show that for $x \in B(y) \subset \Omega''$ that

$$\tilde{A}(x) = A(y) + \mathcal{O}(p(e_0)) \tag{79}$$

   We write

$$\tilde{A}(x) = (H_1^{loc} A_{\Omega'})(x) = \left(H_1^{loc} 1_{\Omega'})(x) A(y) + (H_1^{loc}(A_{\Omega'} - 1_{\Omega'} A(y)) \right)(x) \tag{80}$$

The second term in (80) is $\sum_{y' \in \Omega'} H_1^{loc}(x,y)(A(y') - A(y))$. This vanishes unless x and hence y are in the same component of Ω' as y'. Thus we can use the estimate on ∂A to get $|A(y') - A(y)| \leq d(y,y')\mathcal{O}(p(e_0))$. The term is then $\mathcal{O}(p(e_0))$.

For the first term in (80) we write

$$(H_1^{loc} 1_{\Omega'})(x) = (H_1 1)(x) - (H_1 1_{(\Omega')^c})(x) + ((H_1^{loc} - H_1)1_{\Omega'})(x) \tag{81}$$

For the last term here we again use lemma 17 which has tiny factors $e^{-r(e_0)}$ to dominate the $\mathcal{O}(\mu_0^{-1} p(e_0))$ bound on $A(y)$ and give $\mathcal{O}(p(e_0))$ (or better). For the second term H_1 connects $x \in \Omega''$ to points in $(\Omega')^c$ and thus also has tiny factors from the decay of H_1. For the first term we have

$$\begin{aligned} H_1 1 =& \frac{a}{L^2} C Q^T 1 = C(\frac{a}{L^2} Q^T Q) 1 \\ =& 1 - C(-\Delta_\Omega + \mu_0^2) 1 = 1 + \mathcal{O}(\mu_0^2) \end{aligned} \tag{82}$$

Hence $(H_1 1)(x) A(y) = A(y) + \mathcal{O}(p(e_0))$ and hence the result.

3. Now consider the bound on $A_0 = \check{A} - \tilde{A}$. For $x \in B(y) \subset \Omega''$ we have

$$|A_0(x)| \leq |\check{A}(x) - (Q\check{A})(y)| + |(Q\check{A})(y) - A(y)| + |A(y) - \tilde{A}(x)| \tag{83}$$

   The first term is $\mathcal{O}(p(e_0))$ by the first bound in (77), and the second term is $\mathcal{O}(p(e_0)$ by the third bound in (77). For the last term we use (79).

4. This follows using the bounds (77) and the bounds on A_0. But we want to also show that it follows just from (1.) and (3.). In fact if (1.) holds then the identity (79) holds. Hence the bound on $\tilde{A}$ follows from the bound on A and the bound on $\partial\tilde{A}$ follows from the bound on ∂A. In the latter case look at $(\partial_\mu \tilde{A}_\nu)(x) = \tilde{A}(x + e_\mu) - \tilde{A}(x)$ separately in the cases where x and $x + e_\mu$ are or are not in the same $B(y)$. This completes the proof.

Now introduce new characteristic functions enforcing the conditions on A, A_0 by defining

$$\begin{aligned} \tilde{\chi}_1(\Omega'', A) &= \prod_{x \in \Omega''} \chi\left(\frac{|\partial A(x)|}{2C_1 p(e_0)}\right) \prod_{x \in \Omega''} \chi\left(\frac{|A(x)|}{2C_1 \mu_0^{-1} p(e_0)}\right) \\ \chi^*(\Omega'', A_0) &= \prod_{x \in \Omega''} \chi\left(\frac{|A_0(x)|}{2C_1 p(e_0)}\right) \end{aligned} \tag{84}$$

and inserting $\tilde{\chi}_1(\Omega'', A)\chi^*(\Omega'', A_0)$ under the integral sign in (76).

Consider the old factor

$$\chi_0(\Omega, A, \tilde{A}_{\Omega'} + A_0) = \chi_0(\Omega - \Omega'', A, \tilde{A}_{\Omega'} + A_0)\chi_0(\Omega'', A, \tilde{A} + A_0) \tag{85}$$

With the new characteristic functions in place it is safe to break up the second factor by replacing χ by $1+(1-\chi)$ at each point. We get an expansion of the form

$$\chi_0(\Omega'', A, \tilde{A}+A_0) = \sum_{\tilde{\Lambda}\subset\Omega''} \bar{\zeta}(\Omega''-\tilde{\Lambda}, A, \tilde{A}+A_0) \tag{86}$$

The sum is over unions of R_0 blocks $\tilde{\Lambda}\subset\Omega''$ and the function $\zeta(\Omega''-\tilde{\Lambda}, A, \tilde{A}+A_0)$ forces at least one of the inequalities (77) to be violated in each block in $\Omega''-\tilde{\Lambda}$.

Let us collect some of the the characteristic functions into

$$\begin{aligned}\chi_{0,\Omega,\tilde{\Lambda}}(A, A_0) =&\chi_0(\Omega-\Omega'', A, \tilde{A}_{\Omega'}+A_0)\ \chi^*(\Omega''-\tilde{\Lambda}'', A_0)\\ \zeta_{0,\Omega,\tilde{\Lambda}}(A, A_0) =&\zeta_0(\Omega^c, A, A_0)\ \bar{\zeta}(\Omega''-\tilde{\Lambda}, A, \tilde{A}+A_0)\end{aligned} \tag{87}$$

The overall expression is now

$$\begin{aligned}&\tilde{\rho}_1(\Psi, A) = c_0 e^{\delta E_0}\sum_{\Omega,\tilde{\Lambda}}\int d\Psi_0 dA_0\ \zeta_{0,\Omega,\tilde{\Lambda}}(A, A_0)\ \chi_{0,\Omega,\tilde{\Lambda}}(A, A_0)\ \tilde{\chi}_1(\Omega'', A)\ \chi^*(\tilde{\Lambda}'', A_0)\\ &\exp\left(-\frac{1}{2}(A, \tilde{\Delta}_{1,\Omega}A)-\frac{1}{2}(A_0, \Delta^{\#}A_0)-F^b-W^b)\right)\\ &\exp\Big(-\frac{a}{L}|\Psi-Q_{e_0}(\tilde{A}_{\Omega'}+A_0)\Psi_0|^2+(\bar{\Psi}_0, (D_{e_0}(\tilde{A}_{\Omega'}+A_0)+m_0)\Psi_0)-v(\delta m_0)\Big)\end{aligned} \tag{88}$$

where the sum is restricted by $\tilde{\Lambda}\subset\Omega''$.

3.4 potential

The quadratic form for fermions has the external field $\tilde{A}_{\Omega'}+A_0$. We want to take out the A_0, but only in the region where we have control. Let θ_0 be the characteristic function of Ω'' and write $\tilde{A}_{\Omega'}+A_0 = A^+ + \delta A^+$ where

$$\begin{aligned}A^+ =&(1-\theta_0)(\tilde{A}_{\Omega'}+A_0)+\theta_0\tilde{A}\\ \delta A^+ =&\theta_0 A_0\end{aligned} \tag{89}$$

Then $\delta A^+ = \mathcal{O}(p(e_0))$ and on Ω'' we have $\partial A^+ = \partial\tilde{A} = \mathcal{O}(p(e_0))$. Now write the quadratic form as

$$\begin{aligned}&\frac{a}{L}|\Psi-Q_{e_0}(A^+ + \delta A^+)\Psi_0|^2+(\bar{\Psi}_0, (D_{e_0}(A^+ + \delta A^+)+m_0)\Psi_0)\\ =&\frac{a}{L}|\Psi-Q_{e_0}(A^+)\Psi_0|^2+(\bar{\Psi}_0, (D_{e_0}(A^+)+m_0)\Psi_0)+V_0(\Psi, \Psi_0, A^+, \delta A^+)\end{aligned} \tag{90}$$

(This is the same V_0 as before with new arguments). We also want to include the mass counterterm and part of the energy counterterm defining

$$V_0' = V_0+\delta v_0+\delta\mathcal{E}_0 L^{3(M+N)} \tag{91}$$

We need a local version.

Lemma 3 *The potential* $V_0'(\Psi,\Psi_0,A^+,\delta A^+)$ *has the expansion* $V_0'=\sum_X V_0'(X)$ *where* X *has one or two blocks and* $V_0'(X)$ *only depends on fields in* X*. With* $\delta A^+=\mathcal{O}(p(e_0))$ *we have*

$$\|V_0'(X)\|_h \leq \mathcal{O}(e_0 p(e_0)) \tag{92}$$

Proof. We establish the result for each part separately. Making the conjugate variables explicit we define for M_1-blocks Δ,Δ'

$$V_0(\Delta,\Delta',\bar\Psi,\Psi,\bar\Psi_0,\Psi_0,A^+,\delta A^+)=V_0(\bar\Psi,\Psi,1_\Delta\bar\Psi_0,1_{\Delta'}\Psi_0,A^+,\delta A^+) \tag{93}$$

This vanishes unless Δ,Δ' either coincide or have a common face. For such Δ,Δ' and $X=\Delta\cup\Delta'$ define $V(X)=V(\Delta,\Delta')$. Define $V(X)=0$ for any other polymer X. Then

$$V_0=\sum_{\Delta,\Delta'}V_0(\Delta,\Delta')=\sum_X V_0(X) \tag{94}$$

(Since δA^+ vanishes away from Ω'' we have that $V_0(X)$ vanishes for X away from Ω''). The bound on δA^+ gives $|\exp(ie_0\delta A^+)-1|\leq\mathcal{O}(e_0p(e_0))$ and this leads to $\|V_0(X)\|_h\leq\mathcal{O}(e_0p(e_0))$.

Next define

$$\delta v_0(\Delta)=\sum_{x,y\in\Delta}:\bar\Psi_0(x)\delta m_0\Psi_0(x):_{\hat S_0} \tag{95}$$

and then $\delta v_0=\sum_\Delta\delta v_0(\Delta)\equiv\sum_X\delta v_0(X)$. We have $\|\delta v_0(X)\|_h\leq\mathcal{O}(e_0^2\cdot N)\leq\mathcal{O}(e_0^2p(e_0))$. We also define $\delta\mathcal{E}_0(\Delta)=\delta\mathcal{E}_0M_1^3$ where $\delta\mathcal{E}_0=\mathcal{O}(e_0^2)$ is still to be specified. Then $\delta\mathcal{E}_0\ L^{3(M+N)}=\sum_\Delta\ \delta\mathcal{E}_0(\Delta)\equiv\sum_X\ \delta\mathcal{E}_0(X)$. Thus we have our expansion with $V_0'(X)=V_0(X)+\delta v_0(X)+\delta\mathcal{E}_0(X)$.

3.5 fermion translation

The quadratic form for fermions is now

$$\frac{a}{L}|\Psi-Q_{e_0}(A^+)\Psi_0|^2+(\bar\Psi_0,(D_{e_0}(A^+)+m_0)\Psi_0) \tag{96}$$

We introduce

$$H_1^{loc}(A^+)=\begin{cases}\frac{a}{L}\ \Gamma^{loc}(A^+)Q_{e_0}(-A^+)^T & \text{on }\Psi\\ \frac{a}{L}\ \Gamma^{loc}(A^+)^TQ_{e_0}(A^+)^T & \text{on }\bar\Psi\end{cases} \tag{97}$$

where $\Gamma^{loc}(A^+)$ is defined in (50). This is not well-defined everywhere since ∂A^+ may be large. Nevertheless we can use it in the transformation

$$\Psi_0\to\Psi_0+[H_1^{loc}(A^+)\Psi]_{\tilde\Lambda'}\equiv\Psi_0+\tilde\Psi(A^+)_{\tilde\Lambda'} \tag{98}$$

and similarly for $\bar\Psi$. This only depends on A^+ in $\tilde\Lambda$ where $A^+=\tilde A$ and we have control over $\partial A^+=\partial\tilde A$.

We also introduce

$$\tilde{D}_1^{loc}(A^+) = \frac{a}{L} - \frac{a^2}{L^2} Q_{e_0}(A^+)\Gamma^{loc}(A^+)Q_{e_0}(-A^+)^T \tag{99}$$

this is well-defined when restricted to $\tilde{\Lambda}'$.

Lemma 4 *Under the transformation (98) the quadratic form becomes*

$$(\bar{\Psi}, [\tilde{D}_1^{loc}(A^+)]_{\tilde{\Lambda}'}\Psi) + (\bar{\Psi}_0, D^{\#}(A^+)\Psi_0) + F^f + W^f \tag{100}$$

Here $F^f = F^f(\Psi, \Psi_0, A, A_0)$ *is localized in* $(\tilde{\Lambda}'')^c$ *and* $W^f = W^f(\Psi, \Psi_0, A, A_0)$ *has the local expansion* $W^f = \sum_X W^f(X)$ *where* $W^f(X)$ *has fields localized in* X *and satisfies*

$$\|W^f(X)\|_h \leq \mathcal{O}(e^{-\frac{1}{2}\beta r(e_0)})e^{-\frac{1}{2}\beta M_1|X|_1} \tag{101}$$

Remark. In the course of the proof we will want to make further restrictions to $\tilde{\Lambda}$ such as $\Gamma_{\tilde{\Lambda}}(A^+) = [D^{\#}(A^+)]_{\tilde{\Lambda}}^{-1}$ (first restrict, then inverse) and a local version $\Gamma_{\tilde{\Lambda}}^{loc}(A^+)$ defined by the random walk representation as in (50). These define restricted operators $H_{1,\tilde{\Lambda}}(A^+)$ and $H_{1,\tilde{\Lambda}}^{loc}(A^+)$ just as in (36) (97). Defining these operators as zero off $\tilde{\Lambda}$ they are defined everywhere.

Proof. The term quadratic in Ψ_0 remains $(\bar{\Psi}_0, D^{\#}(A^+)\Psi_0)$. The cross terms have the form

$$\begin{aligned} &-\frac{a}{L}(Q_{e_0}(-A^+)\bar{\Psi}_0, \Psi) + (\bar{\Psi}_0, D^{\#}(A^+)[H_1^{loc}(A^+)\Psi]_{\tilde{\Lambda}'}) \\ &-\frac{a}{L}(\bar{\Psi}, Q_{e_0}(A^+)\Psi_0) + ([H_1^{loc}(A^+)\bar{\Psi}]_{\tilde{\Lambda}'}, D^{\#}(A^+)\Psi_0) \end{aligned} \tag{102}$$

We focus on the first line. Replace $\bar{\Psi}_0$ by $\bar{\Psi}_{0,\tilde{\Lambda}}$ and the difference contributes to F^f. Next replace $D^{\#}(A^+)$ by $D^{\#}(A^+)_{\tilde{\Lambda}}$ at no cost. Then replace Ψ by $\Psi_{\tilde{\Lambda}'}$ and again the difference contributes to F^f. Now in $[H_1^{loc}(A^+)\Psi_{\tilde{\Lambda}'}]_{\tilde{\Lambda}'}$ the only paths which contribute avoid the boundary of $\tilde{\Lambda}$ and so we can replace it by $[H_{1,\tilde{\Lambda}}^{loc}(A^+)\Psi_{\tilde{\Lambda}'}]_{\tilde{\Lambda}'}$. Finally we drop the outside restriction to $\tilde{\Lambda}'$ at the cost of another contribution to F^b. At this point the first line has become

$$-\frac{a}{L}(Q_{e_0}(-A^+)\bar{\Psi}_{0,\tilde{\Lambda}}, \Psi_{\tilde{\Lambda}'}) + (\bar{\Psi}_{0,\tilde{\Lambda}'}, D^{\#}(A^+)_{\tilde{\Lambda}} H_{1,\tilde{\Lambda}}^{loc}(A^+)\Psi_{\tilde{\Lambda}'}) \tag{103}$$

If we replace $H_{1,\tilde{\Lambda}}^{loc}(A^+)$ by $H_{1,\tilde{\Lambda}}(A^+)$ we get zero. The difference is

$$W_3 = (\bar{\Psi}_{0,\tilde{\Lambda}}, D^{\#}(A^+)_{\tilde{\Lambda}}(H_{1,\tilde{\Lambda}}^{loc}(A^+) - H_{1,\tilde{\Lambda}}(A^+))\Psi_{\Lambda'}) \tag{104}$$

To estimate W_3 we use $\Gamma_{\tilde{\Lambda}}(A^+) - \Gamma_{\tilde{\Lambda}}^{loc}(A^+) = \sum_X \delta\Gamma_{\tilde{\Lambda},X}(A^+)$ where $\delta\Gamma_{\tilde{\Lambda},X}(A^+)$ is supported on $X \times X$ and

$$|\delta\Gamma_{\tilde{\Lambda},X}(A^+)| \leq \mathcal{O}(e^{-\beta r(e_0)})e^{-\beta M_1|X|_1}e^{-\beta d(x,y)} \tag{105}$$

See appendix C. The same holds for $H^{loc}_{1,\tilde{\Lambda}}(A^+) - H_{1,\tilde{\Lambda}}(A^+)$ and also breaking $D^{\#}(A^+)_{\Lambda}$ into small polymers (c.f. lemma 3) gives the local representation $W_3 = \sum_X W_3(X)$ with $\|W_3(X)\|_h \leq \mathcal{O}(e^{-\beta r(e_0)})e^{-\frac{1}{2}\beta M_1|X|_1}$.

The term quadratic in Ψ is

$$\begin{aligned}&\frac{a}{L}(\bar{\Psi},\Psi) - \frac{a}{L}(\bar{\Psi}, Q_{e_0}(A^+)[H^{loc}_1(A^+)\Psi]_{\tilde{\Lambda}'}) - \frac{a}{L}(Q_{e_0}(-A^+)[H^{loc}_1(A^+)\bar{\Psi}]_{\tilde{\Lambda}'},\Psi)\\ &+ ([H^{loc}_1(A^+)\bar{\Psi}]_{\tilde{\Lambda}'},\ D^{\#}(A^+)[H^{loc}_1(A^+)\Psi]_{\tilde{\Lambda}'})\end{aligned} \tag{106}$$

We make the replacements $D^{\#}(A^+) \to D^{\#}(A^+)_{\tilde{\Lambda}}$ and $\Psi \to \Psi_{\tilde{\Lambda}'}$ and $[H^{loc}_1(A^+)\Psi]_{\tilde{\Lambda}'} \to H^{loc}_{1,\tilde{\Lambda}}(A^+)\Psi_{\tilde{\Lambda}'}$. Just as for the cross term the difference contributes to F^f. Now replace $H^{loc}_{1,\tilde{\Lambda}}(A^+)\Psi_{\tilde{\Lambda}'}$ by $H_{1,\tilde{\Lambda}}(A^+)\Psi_{\tilde{\Lambda}'}$ and call the difference W_4. We are left with

$$\frac{a}{L}(\bar{\Psi}_{\tilde{\Lambda}'},\Psi_{\tilde{\Lambda}'}) - \frac{a^2}{L^2}(\bar{\Psi}_{\tilde{\Lambda}'}, Q_{e_0}(A^+)\Gamma_{\tilde{\Lambda}}(A^+)Q_{e_0}(-A^+)^T\Psi_{\tilde{\Lambda}'}) \tag{107}$$

Next replace $\Gamma_{\tilde{\Lambda}}(A^+)$ by $\Gamma^{loc}_{\tilde{\Lambda}}(A^+)$ and call the difference W_5. Since they connect points in $\tilde{\Lambda}'$ we can replace $\Gamma^{loc}_{\tilde{\Lambda}}(A^+)$ by $\Gamma^{loc}(A^+)$ at no cost and we get the announced term $(\bar{\Psi}_{\tilde{\Lambda}'}, \tilde{D}^{loc}_1(A^+)\Psi_{\tilde{\Lambda}'})$

A typical term in W_4 is

$$((H^{loc}_{1,\tilde{\Lambda}}(A^+) - H_{1,\tilde{\Lambda}}(A^+))\Psi_{\tilde{\Lambda}'},\ D^{\#}(A^+)_{\tilde{\Lambda}}H_{1,\tilde{\Lambda}}(A^+)\Psi_{\tilde{\Lambda}'}) \tag{108}$$

We insert local expansions for $H^{loc}_{1,\tilde{\Lambda}}(A^+) - H_{1,\tilde{\Lambda}}(A^+)$ as above and similarly for $D^{\#}(A^+)_{\tilde{\Lambda}}$ and $H_{1,\tilde{\Lambda}}(A^+)$. The multiple sum over polymers is rearranged into a single sum which gives the local expansion for this part of W_4. The estimates follow. The other terms in W_4 are treated similarly as is W_5

This completes the proof of the lemma with $W^f = W_3 + W_4 + W_5$.

The full expansion is now with $W = W^b + W^f$

$$\begin{aligned}\tilde{\rho}_1(\Psi, A) = {}& c_0 e^{-\delta E_1}\sum_{\Omega,\tilde{\Lambda}}\int d\Psi_0 dA_0\ \zeta_{0,\Omega,\tilde{\Lambda}}(A,A_0)\ \chi_{0,\Omega,\tilde{\Lambda}}(A,A_0)\ \tilde{\chi}_1(\Omega'',A)\ \chi^*(\tilde{\Lambda}'',A_0)\\ &\exp\left(-\frac{1}{2}(A,\tilde{\Delta}_{1,\Omega}A) - \frac{1}{2}(A_0,\Delta^{\#}A_0) - F^b)\right)\\ &\exp\left(-(\bar{\Psi},[\tilde{D}^{loc}_1(A^+)]_{\tilde{\Lambda}'}\Psi) - (\bar{\Psi}_0, D^{\#}(A^+)\Psi_0) - F^f\right)\\ &\exp\left(-V_0'(\Psi,\Psi_0 + \tilde{\Psi}(A^+)_{\tilde{\Lambda}'}, A^+, \delta A^+) - W\right)\end{aligned} \tag{109}$$

3.6 spacetime split

Now let us focus on the fluctuation integral. We consider the integral in two steps, first integrating over the fields inside $\Lambda \equiv \tilde{\Lambda}''$ by conditioning on the fields outside, and then doing the remaining integral. The conditional expectation can be identified with a Gaussian integral with non-zero mean depending on external variables. The relevant identities can be found in appendix C. When we carry out this step only V_0', W depend on variables inside Λ. Taking account also that $A^+ = \tilde{A}$ in Λ we obtain

$$\begin{aligned}\tilde{\rho}_1(\Psi, A) =& c_0 e^{-\delta E_1} \sum_{\Omega, \tilde{\Lambda}} \int d\Psi_0 dA_0 \ \zeta_{0,\Omega,\tilde{\Lambda}}(A, A_0) \ \chi_{0,\Omega,\tilde{\Lambda}}(A, A_0) \ \tilde{\chi}_1(\Omega'', A) \\ & \exp\left(-\frac{1}{2}(A, \tilde{\Delta}_{1,\Omega} A) - \frac{1}{2}(A_0, \Delta^{\#} A_0) - F^b \right) \\ & \exp\left(-(\bar{\Psi}, [\tilde{D}_1^{loc}(A^+)]_{\tilde{\Lambda}'} \Psi) - (\bar{\Psi}_0, D^{\#}(A^+)\Psi_0) - F^f \right) \\ & \Xi_\Lambda \left(\Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c} \right)\end{aligned} \tag{110}$$

where [4]

$$\begin{aligned}\Xi_\Lambda \left(\Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c} \right) = \int & \ d\mu_{C_\Lambda, \alpha_\Lambda}(A_{0,\Lambda}) \ d\mu_{\Gamma_\Lambda(\tilde{A}), \beta_\Lambda(\tilde{A})}(\Psi_{0,\Lambda}) \chi^*(\Lambda, A_0) \\ & \exp\left(-V_0'(\Psi, \Psi_0 + \tilde{\Psi}(A^+)_{\tilde{\Lambda}'}, A^+, \delta A^+) - W(\Psi, \Psi_0, A, A_0) \right)\end{aligned} \tag{111}$$

Here the Gaussian integrals have covariances and means

$$\begin{aligned}C_\Lambda =& [\Delta^{\#}_\Lambda]^{-1} \\ \alpha_\Lambda =& [\Delta^{\#}_\Lambda]^{-1} \Delta^{\#}_{\Lambda\Lambda^c} A_{0,\Lambda^c} \\ \Gamma_\Lambda(\tilde{A}) =& [D^{\#}(\tilde{A})_\Lambda]^{-1} \\ \beta_\Lambda(\tilde{A}) =& [D^{\#}(\tilde{A})_\Lambda]^{-1} [D^{\#}(\tilde{A})]_{\Lambda\Lambda^c} \Psi_{0,\Lambda^c}\end{aligned} \tag{112}$$

Here $\beta_\Lambda(\tilde{A})$ is the mean for $\Psi_{0,\Lambda}$. There is a similar $\bar{\beta}_\Lambda(\tilde{A})$ as the mean for $\bar{\Psi}_{0,\Lambda}$. See the appendix. We note that the integrand in (111) contains extensive dependence on variables outside Λ.

3.7 backing up

Let us define Ξ^W_Λ to be the same as Ξ_Λ but with $V_0' = 0$ and $\chi^* = 1$. We will see that Ξ^W_Λ is invertible, i.e. the no-fermion part is non-zero. Thus we can write

$$\Xi_\Lambda = \Xi^W_\Lambda \left(\frac{\Xi_\Lambda}{\Xi^W_\Lambda} \right) \equiv \Xi^W_\Lambda \tilde{\Xi}_\Lambda \tag{113}$$

---

[4] The expression Ξ_Λ might more accurately be denoted $\Xi_{\Omega,\tilde{\Lambda}}$. Our notation reflects the fact that the important dependence is on $\Lambda = \tilde{\Lambda}''$.

Now put this in (110) and then undo the conditioning with the first factor Ξ^W_Λ. The second factor $\tilde{\Xi}_\Lambda$ is not affected since it only depends on variables in Λ^c. This gives

$$\begin{aligned}\tilde{\rho}_1(\Psi, A) =& c_0 e^{-\delta E_1} \sum_{\Omega,\tilde{\Lambda}} \int d\Psi_0 dA_0 \ \zeta_{0,\Omega,\tilde{\Lambda}}(A, A_0) \ \chi_{0,\Omega,\tilde{\Lambda}}(A, A_0) \ \tilde{\chi}_1(\Omega'', A) \\ & \exp\left(-\frac{1}{2}(A, \tilde{\Delta}_{1,\Omega} A) - \frac{1}{2}(A_0, \Delta^{\#} A_0) - F^b - W^b \right) \\ & \exp\left(-(\bar{\Psi}_\Lambda, [\tilde{D}^{loc}_1(A^+)]_{\tilde{\Lambda}'} \Psi_\Lambda) - (\bar{\Psi}_0, D^{\#}(A^+)\Psi_0) - F^f - W^f \right) \\ & \tilde{\Xi}_\Lambda \left(\Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c} \right)\end{aligned} \tag{114}$$

We also undo the translations. We make the inverse transformation $\Psi_0 \to \Psi_0 - \tilde{\Psi}(A^+)_{\tilde{\Lambda}'}$. By lemma 4 the second exponential above is changed back to to the exponential of the original fermion quadratic form (96). We also make the inverse transformation $A_0 \to A_0 - \tilde{A}_{\Omega'}$ By lemma 1 the first exponential above is changed back to to the exponential of the original boson quadratic form (27) .

In addition there the following changes changes. The characteristic functions become

$$\begin{aligned}\chi'_{0,\Omega,\tilde{\Lambda}}(A, A_0) \equiv& \chi_{0,\Omega,\tilde{\Lambda}}(A, A_0 - \tilde{A}_{\Omega'}) \\ =& \chi_0(\Omega - \Omega'', A, A_0) \ \chi^*(\Omega'' - \Lambda, A_0 - \tilde{A}_{\Omega'}) \\ \zeta'_{0,\Omega,\tilde{\Lambda}}(A, A_0) \equiv& \zeta_{0,\Omega,\tilde{\Lambda}}(A, A_0 - \tilde{A}_{\Omega'}) \\ =& \zeta_0(\Omega^c, A, A_0) \ \bar{\zeta}(\Omega'' - \tilde{\Lambda}, A, A_0)\end{aligned} \tag{115}$$

The background field for the fermions changes from A^+ to

$$A^* \equiv (1-\theta_0)A_0 + \theta_0 \tilde{A} \tag{116}$$

Finally the fluctuation part is transformed to

$$\tilde{\Xi}'_\Lambda \left(\Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c} \right) = \tilde{\Xi}_\Lambda \left(\Psi, \Psi_{0,\Lambda^c} - \tilde{\Psi}(A^*)_{\tilde{\Lambda}'-\Lambda}, A, A_{0,\Lambda^c} - \tilde{A}_{\Omega'-\Lambda} \right) \tag{117}$$

Thus our expression has become

$$\begin{aligned}\tilde{\rho}_1(\Psi, A) =& c_0 e^{-\delta E_1} \sum_{\Omega,\tilde{\Lambda}} \int d\Psi_0 dA_0 \ \zeta'_{0,\Omega,\tilde{\Lambda}}(A, A_0) \ \chi'_{0,\Omega,\tilde{\Lambda}}(A, A_0) \ \tilde{\chi}_1(\Omega'', A) \\ & \exp\left(-\frac{a}{2L^2}|A - QA_0|^2 - \frac{1}{2}(A_0, (-\Delta + \mu_0^2)A_0) \right) \\ & \exp\left(-\frac{a}{L}|\Psi - Q_{e_0}(A^*)\Psi_0|^2 - (\bar{\Psi}_0, (D_{e_0}(A^*) + m_0)\Psi_0) \right) \\ & \tilde{\Xi}'_\Lambda \left(\Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c} \right)\end{aligned} \tag{118}$$

3.8 scaling

Now we scale to $\rho_1(\Psi_1, A_1) \equiv \tilde{\rho}_1(\Psi_{1,L}, A_{1,L})$ where Ψ_1, A_1 on $\mathbb{T}^0_{N+M-1}$ scale up to $\Psi_{1,L}, A_{1,L}$ is on $\mathbb{T}^1_{N+M}$. Define $\mathcal{H}^{loc}_1 = \sigma_L^{-1} H^{loc}_1 \sigma_L$. Then $\tilde{A} = H^{loc}_1 A$ becomes $H^{loc}_1 A_{1,L} = \mathcal{A}_{1,L}$ where $\mathcal{A}_1 = \mathcal{H}^{loc}_1 A_1$ and the background field A^* becomes

$$\hat{A}_1 = (1-\theta_0)A_0 + \theta_0 \mathcal{A}_{1,L} \tag{119}$$

We also define $\zeta_{1,\Omega,\tilde{\Lambda}}(A_1, A_0) = \zeta'_{0,\Omega,\tilde{\Lambda}}(A_{1,L}, A_0)$ and $\chi_{1,\Omega,\tilde{\Lambda}}(A_1, A_0) = \chi'_{0,\Omega,\tilde{\Lambda}}(A_{1,L}, A_0)$ and

$$\begin{aligned} \chi_1(L^{-1}\Omega'', A_1) =& \tilde{\chi}_1(\Omega'', A_{1,L}) \\ \Xi_{1,\Lambda}\left(\Psi_1, \Psi_{0,\Lambda^c}, A_1, A_{0,\Lambda^c}\right) =& \tilde{\Xi}'_{\Lambda}\left(\Psi_{1,L}, \Psi_{0,\Lambda^c}, A_{1,L}, A_{0,\Lambda^c}\right) \end{aligned} \tag{120}$$

Then we have the final expression

$$\begin{aligned} \rho_1(\Psi_1, A_1) =& c_0 e^{-\delta E_1} \sum_{\Omega,\tilde{\Lambda}} \int d\Psi_0 dA_0 \ \zeta_{1,\Omega,\tilde{\Lambda}}(A_1, A_0) \ \chi_{1,\Omega,\tilde{\Lambda}}(A_1, A_0) \\ & \exp\left(-\frac{a}{2L^2}|A_{1,L} - QA_0|^2 - \frac{1}{2}(A_0, (-\Delta + \mu_0^2)A_0) \right) \\ & \exp\left(-\frac{a}{L}|\Psi_{1,L} - Q_{e_0}(\hat{A}_1)\Psi_0|^2 - (\bar{\Psi}_0, (D_{e_0}(\hat{A}_1) + m_0)\Psi_0) \right) \\ & \Xi_{1,\Lambda}\left(\Psi_1, \Psi_{0,\Lambda^c}, A_1, A_{0,\Lambda^c}\right) \chi_1(L^{-1}\Omega'', A_1) \end{aligned} \tag{121}$$

4 Fluctuation integral

4.1 a local expansion

We study the fluctuation integral $\tilde{\Xi} = \Xi_\Lambda / \Xi^W_\Lambda$. First we consider the normalization factor Ξ^W_Λ which is given by

$$\begin{aligned}\Xi^W_\Lambda\left(\Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c}\right) = \int & \ d\mu_{C_\Lambda, \alpha_\Lambda}(A_{0,\Lambda}) \ d\mu_{\Gamma_\Lambda(\tilde{A}), \beta_\Lambda(\tilde{A})}(\Psi_{0,\Lambda}) \\ & \exp\left(-W(\Psi, \Psi_0, A, A_0)\right)\end{aligned} \tag{122}$$

This is a tiny perturbation of a Gaussian and we have the local representation:

Lemma 5 *Assume* $|A| \leq \mathcal{O}(\mu_0^{-1} p(e_0))$ *on* Ω *and* $|A_0| \leq \mu_0^{-1} p(e_0)$ *on* $\Omega - \Lambda$. *Then*

$$\Xi^W_\Lambda\left(\Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c}\right) = \exp\left(-\sum_X W^*(X, \Psi, \Psi_{0,\Lambda^c}, A, A_{0,\Lambda^c})\right) \tag{123}$$

where

$$\|W^*(X)\|_h \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)}) e^{-\mathcal{O}(1)\beta M_1 |X|_1} \tag{124}$$

Remark. The assumed bounds on A, A_0 are needed for control over W as we have seen in lemma 1. Let us note that they still follow from the modified characteristic functions of the expansion (110). Indeed the bound on A on Ω'' follows from the bounds of $\tilde{\chi}_1(\Omega'', A)$ while the bound on A on $\Omega - \Omega''$ follows from the bounds of $\chi_0(\Omega - \Omega'', A, \tilde{A}_{\Omega'} + A_0)$. The bound on A_0 on $\Omega'' - \Lambda$ follows from the bounds of $\chi^*(\Omega'' - \Lambda, A_0)$ while the bound on A_0 on $\Omega - \Omega''$ follows from the bound $|\tilde{A}_{\Omega'} + A_0| \leq \mathcal{O}(\mu_0^{-1} p(e_0))$ on $\Omega - \Omega''$ and the bound on A. Also note that we maintain control after the backing-up transformation since Ξ^W_Λ and the characteristic functions undergo the same transformation.

Proof. The expression factors into a fermion piece and a boson piece. We discuss the boson piece in detail; fermions are similar. The boson piece is

$$\begin{aligned}\Xi^{W,b}_\Lambda(A, A_{0,\Lambda^c}) &= \int \ d\mu_{C_\Lambda, \alpha_\Lambda}(A_{0,\Lambda}) \ \exp\left(-W^b(A, A_0)\right) \\ &= \int \ d\mu_{C_\Lambda}(A_{0,\Lambda}) \ \exp\left(-W^b(A, A_0 + \alpha_\Lambda)\right)\end{aligned} \tag{125}$$

We recall from lemma 1 that $W^b(A, A_0) = (A_0, w_1 A) + \frac{1}{2}(A_0, w_2 A_0)$ so that

$$W^b(A, A_0 + \alpha_\Lambda) = ((A_0 + \alpha_\Lambda), w_1 A) + \frac{1}{2}((A_0 + \alpha_\Lambda), w_2(A_0 + \alpha_\Lambda)) \tag{126}$$

We also have $w_1 = \sum_X w_1(X)$ and

$$|w_1(X,x,y)| \leq \mathcal{O}(1) e^{-\mathcal{O}(1)\beta r(e_0)} e^{-\mathcal{O}(1)\beta M_1 |X|_1} e^{-\mathcal{O}(1)\beta d(x,y)} \tag{127}$$

and similarly for w_2.

The terms $W_1^* = (\alpha_\Lambda, w_1 A) + \frac{1}{2}(\alpha_\Lambda, w_2 \alpha_\Lambda)$ come outside the integral. From lemma 16 we have $C_\Lambda = \sum_X C_\Lambda(X)$ and hence $\alpha_\Lambda = \sum_X \alpha_\Lambda(X)$ with the bound $|\alpha_\Lambda(X)| \leq \mathcal{O}(p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X|_1}$. Use this together with the expansions for w_1, w_2 and combine into to single expansion to get $W_1^* = \sum_X W_1^*(X)$ where $W_1^*(X)$ satisfies the bound of the lemma. The point is that the strong $e^{-\mathcal{O}(1)\beta r(e_0)}$ factor from w_1, w_2 compensates the weak $\mathcal{O}(p(e_0))$ bound in α_Λ and the $\mu_0^{-1} p(e_0)$ bound on A.

We are left with the expression

$$\int \exp\left(-(A_0, f) - \frac{1}{2}(A_0, w_2 A_0) \right) d\mu_{C_\Lambda}(A_{0,\Lambda}) \tag{128}$$

where $f = w_1 A + w_2 \alpha_\Lambda$. As above we have the local expansion $f = \sum_X f(X)$ with $|f(X)| \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)}) e^{-\mathcal{O}(1)\beta M_1 |X|_1}$. Next break A_0 into A_{0,Λ^c} and $A_{0,\Lambda}$. The terms $W_2^* = (A_{0,\Lambda^c}, f) + \frac{1}{2}(A_{0,\Lambda^c}, w_2 A_{0,\Lambda^c})$ again have a local expansion and we are left with

$$\int \exp\left(-(A_{0,\Lambda}, f') - \frac{1}{2}(A_{0,\Lambda}, w_2 A_{0,\Lambda}) \right) d\mu_{C_\Lambda}(A_{0,\Lambda}) \tag{129}$$

where $f' = f + w_2 A_{0,\Lambda^c}$. Note that f' again has a local expansion with the same bounds as f. This Gaussian integral can be explicitly evaluated as

$$\det(1 + w_2 C_\Lambda)^{-\frac{1}{2}} \exp\left(\frac{1}{2}(f', (w_2 + C_\Lambda^{-1})^{-1} f') \right) \tag{130}$$

Consider the first factor in (130). Since $w_2 C_\Lambda$ has a small $\mathcal{L}^2$-operator norm we can write

$$\det(1 + w_2 C_\Lambda)^{-\frac{1}{2}} = \exp\left(-\frac{1}{2} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} tr((w_2 C_\Lambda)^n) \right) = \exp\left(-\sum_Z W_3^*(Z) \right) \tag{131}$$

In the second step we have inserted the local expansions for w_2, C_Λ and defined

$$W_3^*(Z) = \frac{1}{2} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sum_{X_1, Y_1, \dots, X_n, Y_n \to Z} tr(w_2(X_1) C_\Lambda(Y_1) \dots w_2(X_n) C_\Lambda(Y_n)) \tag{132}$$

The sum is over sets $X_1, Y_1, \dots, X_n, Y_n$ whose union is Z. The terms in this sequence must intersect their neighbors, else we get no contribution. Thus Z is connected. We have the estimate

$$|(w_2(X) C_\Lambda(Y))(x,y)| \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)}) e^{-\mathcal{O}(1)\beta M_1 (|X|_1 + |Y|_1)} e^{-\mathcal{O}(1)\beta d(x,y)} \tag{133}$$

Thus the operator norm satisfies $\|w_2(X)C_\Lambda(Y)\| \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)})e^{-\mathcal{O}(1)\beta M_1(|X|_1+|Y|_1)}$. The Hilbert Schmidt norm $\|w_2(X)C_\Lambda(Y)\|_2$ satisfies the same bound with a negligible factor of $|X| = M_1^3|X|_1$ and the trace norm $\|w_2(X)C_\Lambda(Y)\|_1$ satisfies the same, again with a negligible factor. Now using $|tr(AB)| \leq \|A\|_1\|B\|$ we obtain

$$|W_3^*(Z)| \leq \sum_{n=1}^{\infty} \sum_{X_1,Y_1,\dots,X_n,Y_n \to Z} \prod_{i=1}^{n} \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)})e^{-\mathcal{O}(1)\beta M_1(|X_i|_1+|Y_i|_1)} \tag{134}$$

Next extract an overall factor $\exp(-\mathcal{O}(1)\beta M_1|Z|_1)$. The sum over $|Y_n|$ is then estimated by

$$\sum_{Y_n \cap X_n \neq \emptyset} e^{-\mathcal{O}(1)\beta M_1|Y_n|_1} \leq |X_n|_1 \tag{135}$$

and the $|X_n|$ is absorbed by the factor $e^{-\mathcal{O}(1)\beta M_1|X_n|_1}$. Continue estimating the sums in this fashion. In the last step we get a factor $|Z|_1$ which is also absorbed. Thus we end with

$$|W_3^*(Z)| \leq e^{-\mathcal{O}(1)\beta M_1|Z|_1} \sum_{n=1}^{\infty} (\mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)}))^n \tag{136}$$

which has the bound of the lemma.

Now consider the second factor in (130) which we write

$$\begin{aligned}\exp\left(\frac{1}{2}(f', (w_2 + C_\Lambda^{-1})^{-1} f')\right) &= \exp\left(\frac{1}{2}(f', C_\Lambda(1 + w_2 C_\Lambda)^{-1} f')\right)\\ = \exp\left(\frac{1}{2}(f', C_\Lambda \sum_{n=0}^{\infty} (w_2 C_\Lambda)^n f')\right) &= \exp\left(\sum_Z W_4^*(Z)\right)\end{aligned} \tag{137}$$

In the last step we have inserted local expansions and grouped terms by their localization. The estimate on $W_4^*(Z)$ is similar to the estimate on $W_3^*(Z)$, but now only operator norms enter. This completes the proof.

4.2 adjustments

Insert the expression (123) for Ξ_Λ^W into $\tilde{\Xi} = \Xi_\Lambda/\Xi_\Lambda^W$ and put the terms under the integral sign. Also insert the local expansions for V_0' and W and obtain

$$\tilde{\Xi}_\Lambda = \int \exp\left(\sum_X E_0(X)\right) \chi^*(\Lambda, A_0)\ d\mu_{C_\Lambda,\alpha_\Lambda}(A_{0,\Lambda})\ d\mu_{\Gamma_\Lambda(\tilde{A}),\beta_\Lambda(\tilde{A})}(\Psi_{0,\Lambda}) \tag{138}$$

where

$$\begin{aligned}E_0(X) = &- V_0'(X, \Psi, \Psi_0 + \tilde{\Psi}(A^+)_{\tilde{\Lambda}'}, A^+, \delta A^+)\\ &- W(X, \Psi, \Psi_0, A, A_0) + W^*(X, \Psi, \Psi_0, A, A_0)\end{aligned} \tag{139}$$

This is the main object of our attention. Before we attack it however we want to make some adjustments. We concentrate on the case $X \subset \Lambda'$ in which case the potential can be written $V_0'(X, \Psi, \Psi_0 + \tilde{\Psi}(\tilde{A}), \tilde{A}, A_0)$ We break it into pieces by writing (at first without the translation)

$$V_0'(X, \Psi, \Psi_0, \tilde{A}, A_0) = V_0^Q(X, \Psi, \Psi_0, \tilde{A}, A_0) + V_0^D(X, \Psi_0, \tilde{A}, A_0) + \delta V_0(X, \Psi_0) \tag{140}$$

where V^Q is the part that comes from the variation of $aL^{-1}|\Psi - Q_{e_0}(A)\Psi_0|^2$ and V_0^D is the part that comes from the variation of $(\bar{\Psi}_0, D_{e_0}(A)\Psi_0)$ and δV_0 are the counterterms. Our goal is to get rid of the Ψ dependence in V_0^Q and make it a function of $\tilde{\Psi}(\tilde{A}) = H_1^{loc}(\tilde{A})\Psi$ only. This will be important later on.

To accomplish this we define for any A

$$M_\Lambda(A) = \begin{cases} \frac{L}{a}\ Q_{e_0}(A)[D^{\#}(A)]_\Lambda & \text{on } \Psi \\ \frac{L}{a}\ Q_{e_0}(-A)[D^{\#}(A)]_\Lambda & \text{on } \bar{\Psi} \end{cases} \tag{141}$$

which satisfies

$$M_\Lambda(A) H_{1,\Lambda}(A) = I \tag{142}$$

Then we write with $\delta Q(\tilde{A}, A_0) = Q_{e_0}(\tilde{A} + A_0) - Q_{e_0}(\tilde{A})$

$$\begin{aligned} \sum_{X \subset \Lambda'} V_0^Q(X, \Psi, \Psi_0, \tilde{A}, A_0) &= -\frac{a}{L}(\bar{\Psi}, \delta Q \Psi_{0,\Lambda'}) + \dots \\ &= -\frac{a}{L}(M_\Lambda(\tilde{A})H_{1,\Lambda}(\tilde{A})\bar{\Psi}, \delta Q \Psi_{0,\Lambda'}) + \dots \\ &= -\frac{a}{L}(M_\Lambda(\tilde{A})H_{1,\Lambda}^{loc}(\tilde{A})\bar{\Psi}, \delta Q \Psi_{0,\Lambda'}) + \cdots \\ &\quad - \frac{a}{L}(M_{\Lambda_*}(\tilde{A})(H_{1,\Lambda}(\tilde{A}) - H_{1,\Lambda}^{loc}(\tilde{A}))\bar{\Psi}, \delta Q \Psi_{0,\Lambda'}) + \dots \\ &\equiv \sum_X \tilde{V}_0^Q(X, \tilde{\Psi}(\tilde{A}), \Psi_0, \tilde{A}, A_0) + V_0^\dagger(X, \Psi, \Psi_0, \tilde{A}, A_0) \end{aligned} \tag{143}$$

Here $+\dots$ indicates a similar term with $\bar{\Psi}_0\Psi$ rather than $\bar{\Psi}\Psi_0$. In passing to the last line in the first term we have replaced $H_{1,\Lambda}^{loc}(\tilde{A}x, y)$ by $H_1^{loc}(\tilde{A}, x, y)$ which is allowed since x, y are far from $\partial\Lambda$. Then we have localized the first term in $\tilde{\Psi}(\tilde{A}), \Psi_0$ The second term is localized using a local expansion for $H_{1,\Lambda}(\tilde{A}) - H_{1,\Lambda}^{loc}(\tilde{A})$, see lemma 4 for details in a similar case. Also it is tiny. We have the estimates $\|\tilde{V}_0^Q(X)\|_h \leq \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X|_1}$ and $\|V_0^\dagger(X)\|_h \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)}) e^{-\mathcal{O}(1)\beta M_1 |X|_1}$.

Having made this rearrangement in Λ' the integrand is now $\exp(\sum_X E_0'(X))$ where $E_0'(X) = E_0'(X, \tilde{\Psi}(A^+), \Psi, \Psi_{0,\Lambda^c}, \tilde{A}, A, A_{0,\Lambda^c})$ is given by

$$E_0'(X) = \begin{cases} E_0(X) - V^{\#}(X) & X \cap (\Lambda')^c \neq \emptyset \\ -V_0^*(X) + R_0(X) & X \subset \Lambda' \end{cases} \tag{144}$$

where

$$\begin{aligned} V^{\#}(X) =&[\tilde{V}_0^Q(X) + V_0^{\dagger}(X)]_{\Psi_0=\Psi_0+\Psi(\tilde{A})} \\ V_0^*(X) =&[\tilde{V}_0^Q(X) + V_0^D(X) + \delta V_0(X)]_{\Psi_0=\Psi_0+\Psi(\tilde{A})} \\ R_0(X) =&[-V_0^{\dagger}(X)]_{\Psi_0=\Psi_0+\Psi(\tilde{A})} - W(X) + W^*(X) \end{aligned} \tag{145}$$

The important term is V_0^* and we note that it is now a function only of the variables we want.

Before the translation we have bounds on all these functions. The effect of the translation $\Psi_0 \to \Psi_0 + \Psi(\tilde{A})$ is to lower the value of $h = \mathcal{O}(1)$ to $h' = \mathcal{O}(1)$ satisfying $h'(1+\|\mathcal{H}_1^{loc}\|^{(2)}) \leq h$. See lemma 20 in appendix B. Thus we have the following bounds

$$\begin{aligned} \|V_0^*(X)\|_{h'} \leq& \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X|_1} \\ \|R_0(X)\|_{h'} \leq& \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)}) e^{-\mathcal{O}(1)\beta M_1 |X|_1} \\ \|E_0'(X)\|_{h'} \leq& \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X|_1} \end{aligned} \tag{146}$$

4.3 cluster expansion

The fluctuation integral is now

$$\tilde{\Xi}_\Lambda = \int \exp\left(\sum_X E_0'(X)\right) \chi^*(\Lambda, A_0)\ d\mu_{C_\Lambda,\alpha_\Lambda}(A_{0,\Lambda})\ d\mu_{\Gamma_\Lambda(\tilde{A}),\beta_\Lambda(\tilde{A})}(\Psi_{0,\Lambda}) \tag{147}$$

Our cluster expansion expresses this as a sum of local parts, but only well inside Λ. Cluster expansions similar to ours appear in [19], [7], [5].

Theorem 1 *Let e_0 be sufficiently small (depending on L, M_0, M_1). Also let $|\partial A| \leq \mathcal{O}(p(e_0))$ on Ω'' and $|A| \leq \mathcal{O}(\mu_0^{-1} p(e_0))$ on Ω and $|A_0| \leq p(e_0)$ on $\Omega - \Lambda$. Then*

$$\tilde{\Xi}_\Lambda = \sum_{\Theta \subset \Lambda'} \mathcal{T}(\Theta^c) \exp\left(\sum_{X \subset \Theta} \tilde{E}(X)\right) \tag{148}$$

where

1. *$\tilde{E}(X) = \tilde{E}(X, \tilde{\Psi}(\tilde{A}), \Psi, \tilde{A}, A)$ only depends on the indicated fields in X (and is independent of $\Psi_{0,\Lambda^c}, A_{0,\Lambda^c}$). There is a constant $h_1 = \mathcal{O}(1)$ and a universal constant κ such that*

$$\|\tilde{E}(X)\|_{h_1} \leq \mathcal{O}(e_0 p(e_0)) e^{-\kappa |X|_1} \tag{149}$$

2. *Let $\{\Theta_\beta^c\}$ be the connected components of Θ^c. The the sum over Θ is further restricted by the constraint that each Θ_β^c contain a connected component of Λ^c. Also we have the factorization $\mathcal{T}(\Theta^c) = \prod_\beta \mathcal{T}(\Theta_\beta^c)$ and the bound*

$$\|\mathcal{T}(\Theta_\beta^c)\|_{h_1} \leq e^{\mathcal{O}(1)|\Theta_\beta^c - \Lambda'|_1} e^{-\kappa |\Theta_\beta^c \cap \Lambda'|_1} \tag{150}$$

Remarks.

1. The assumed bounds on A, A_0 still hold in our expansion. See the remark following lemma 5.
2. We have retreated from decay in the linear size $M_1|X|_1$ to just decay in $|X|_1$. Nevertheless the decay in $\mathcal{T}(\Theta)$ will be sufficient for convergence of the sum over Θ.
3. The function $\mathcal{T}(\Theta_\beta^c) = \mathcal{T}(\Theta_\beta^c, \tilde{\Psi}(A^+), \Psi, \Psi_{0,\Lambda^c}, \tilde{A}, A, A_{0,\Lambda^c})$ only depends on the indicated fields in Θ_β^c. Both $\mathcal{T}(\Theta)$ and $\tilde{E}(X)$ depend on Ω, Λ.

Proof. We suppress external variables throughout.

part I: If X is contained in Λ^c then $E_0'(X)$ does not depend on $\Psi_{0,\Lambda}, A_{0,\Lambda}$ and we can take these terms outside the integral. It remains to consider terms intersecting Λ.

We make a Mayer expansion and write

$$\begin{aligned}
&\exp(\sum_{X: X\cap\Lambda\neq\emptyset} E_0'(X)) = \prod_X e^{E_0'(X)} \\
=&\prod_X \Big((e^{E_0'(X)} - 1) + 1\Big) = \sum_{\{X_i\}} \prod_i (e^{E_0'(X)} - 1) = \sum_X K_0(X)
\end{aligned} \tag{151}$$

Here the sum over $\{X_i\}$ is a sum over collections of distinct subsets intersecting Λ. In the last step we have grouped to together terms with the same $X = \cup_i X_i$ and defined

$$K_0(X) = \sum_{\{X_i\}:\cup_i X_i = X} \prod_i (e^{E_0'(X_i)} - 1) \tag{152}$$

Note that if $\{X_\alpha\}$ are the connected components of X, then $K_0(X) = \prod_\alpha K(X_\alpha)$.

We estimate $K_0(X)$ for X connected. Under our assumptions on A, A_{0,Λ^c} together with the bound $|A_{0,\Lambda}| \leq \mathcal{O}(p(e_0))$ from $\chi^*(\Lambda, A_0)$ the bound (146) on $E_0'(X)$ holds. Then for X connected we have

$$\begin{aligned}
&\|K_0(X)\|_{h'} \leq \sum_{\{X_i\}:\cup_i X_i = X} \prod_i \|e^{E_0'(X_i)} - 1\|_{h'} \\
&\leq \sum_{\{X_i\}:\cup_i X_i = X} \prod_i \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X_i|_1} \leq \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X|_1}
\end{aligned} \tag{153}$$

In the last step the origin of the small factors is clear. For the convergence of the sum we use that for collections $\{X_i\}$ of connected subsets of X, any α, and κ large enough

$$\begin{aligned}
&\sum_{\{X_i\}} \prod_i \alpha e^{-\kappa|X_i|} \leq \sum_n \frac{1}{n!} \sum_{(X_1,\dots,X_n)} \prod_i \alpha e^{-\kappa|X_i|} \\
&= \exp(\sum_{X'\subset X} \alpha e^{-\kappa|X'|}) \leq \exp(\alpha|X|_1)
\end{aligned} \tag{154}$$

We also remove the characteristic functions in $\Lambda - X$ where they are not needed We write

$$\chi^*(\Lambda, A_0) = \chi^*(\Lambda \cap X, A_0) \sum_{P \subset \Lambda - X} \zeta^*(P, A_0) \tag{155}$$

Here $\zeta^*(P, A_0)$ enforces that every block in P has at least one point where the inequality $|A_0| \leq 4C_1 p(e_0)$ is violated. Explicitly

$$\zeta^*(P, A_0) = \sum_{Q: \bar{Q}^{M_1} = P} \prod_{x \in Q} (\chi\left(\frac{|A_0(x)|}{2C_1 p(e_0)}\right) - 1) \tag{156}$$

Here Q is a subset of lattice points in P and $\bar{Q}^{M_1}$ is the smallest union of M_1 blocks containing Q. The purpose of this step is to arrange that every block Δ either has nothing in it, or something small.

Now we need to analyze:

$$\sum_{X,P} \int K_0(X, \Psi_0, A_0)\ \chi^*(\Lambda \cap X, A_0)\ \zeta^*(P, A_0)\ d\mu_{C_\Lambda, \alpha_\Lambda}(A_0)\ d\mu_{\Gamma_\Lambda(\tilde{A}), \beta_\Lambda(\tilde{A})}(\Psi_0) \tag{157}$$

part II.: To break up the integral we have to break up the covariances C_Λ and $\Gamma_\Lambda(\tilde{A})$. This will be accomplished using the random walk expansion.

We introduce a variable $s = \{s_\Delta\}$ with $0 \leq s_\Delta \leq 1$ for every M_1 cube Δ. If $\omega = (j_0, j_1, \dots, j_n)$ is a path in the M_0 lattice with localization domain $(\mathcal{O}_{j_0}, \mathcal{O}_{j_1}, \cdots, \mathcal{O}_{j_n})$ we define

$$s_\omega = \prod_{\Delta : \Delta \cap (\mathcal{O}_{j_1} \cup \cdots \cup \mathcal{O}_{j_n}) \neq \emptyset} s_\Delta \tag{158}$$

Note that $\mathcal{O}_{j_0}$ is omitted. Hence if ω is only the single point $\{j_0\}$ (i.e. $\ell(\omega) = 0$) the product is empty and in this case we set $s_\omega = 1$. Now we define

$$\begin{aligned} C_\Lambda(s) =& \sum_\omega s_\omega C_{\Lambda,\omega} \\ \Gamma_\Lambda(s, \tilde{A}) =& \sum_\omega s_\omega \Gamma_{\Lambda,\omega}(\tilde{A}) \end{aligned} \tag{159}$$

When all variables $s_\Delta = 1$ we recover the original operators $C_\Lambda, \Gamma_\Lambda(\tilde{A})$. If all the $s_\Delta = 0$ we have only paths with $\ell(\omega) = 0$ and have the totally decoupled operators

$$\begin{aligned} C_\Lambda(0) =& C^*_\Lambda \equiv \sum_j h_j C_{\mathcal{O}_j} h_j \\ \Gamma_\Lambda(0, \tilde{A}) =& \Gamma^*_\Lambda(\tilde{A}) \equiv \sum_j h_j \Gamma_{\mathcal{O}_j}(\tilde{A}) h_j \end{aligned} \tag{160}$$

Now we write

$$\begin{aligned} C_\Lambda(s) =& C_\Lambda(0) + \delta C_\Lambda(s) \\ \Gamma_\Lambda(s, \tilde{A}) =& \Gamma_\Lambda(0, \tilde{A}) + \delta\Gamma_\Lambda(s, \tilde{A}) \end{aligned} \tag{161}$$

One can show $\Delta^{\#}_{\mathcal{O}} \leq \mathcal{O}(L^3)$. It follows that $\mathcal{C}_{\mathcal{O}} = [\Delta^{\#}_{\mathcal{O}}]^{-1} \geq \mathcal{O}(L^{-3})$. and hence $C_{\Lambda}(0) \geq \mathcal{O}(L^{-3})$. On the other hand by the bounds of lemma 14 in appendix A we have $\|\delta C_{\Lambda}(s)\| \leq \mathcal{O}(M_0^{-1})$. Since M_0 is assumed larger than L we see that $C_{\Lambda}(s)$ is positive.

We introduce the s parameters into (157), replacing $C_{\Lambda}, \Gamma_{\Lambda}(\tilde{A})$ by $C_{\Lambda}(s), \Gamma_{\Lambda}(s, \tilde{A})$. This includes replacing $\alpha_{\Lambda}, \beta_{\Lambda}(\tilde{A})$ by

$$\begin{aligned} \alpha_{\Lambda}(s) =& C_{\Lambda}(s)\Delta^{\#}_{\Lambda\Lambda^c} A_{0,\Lambda^c} \\ \beta_{\Lambda}(s, \tilde{A}) =& \Gamma_{\Lambda}(s, \tilde{A})[D^{\#}(A^+)]_{\Lambda\Lambda^c}\Psi_{0,\Lambda^c} \end{aligned} \tag{162}$$

We have the expression for $s_{\Delta} = 1$ and we study it by expanding around $s_{\Delta} = 0$, but only for Δ in $\Lambda' - (X \cup P)$, essentially the region with no contribution to the integrand. (We leave $\Lambda - \Lambda'$ alone to avoid trouble with the fact that α_{Λ} is not small enough here.) Now (157) can be written

$$\begin{aligned} &\sum_{X,P,Y} \int ds_Y \frac{\partial}{\partial s_Y}[\int K_0(X)\chi^*(\Lambda \cap X)\zeta^*(P) d\mu_{C_{\Lambda}(s),\alpha_{\Lambda}(s)}(A_0)\ d\mu_{\Gamma_{\Lambda}(s,\tilde{A}),\beta_{\Lambda}(s,\tilde{A})}(\Psi_0)\ ]_{s_{Y^c}=0} \\ &= \sum_Z \tilde{K}(Z) \end{aligned} \tag{163}$$

where $s_Y = \{s_{\Delta}\}_{\Delta \subset Y}$. The sum is over $Y \subset \Lambda' - (X \cup P)$ and Y^c is the complement in this set so that $s_{Y^c} = 0$ is really $s_{\Lambda' - (X \cup P \cup Y)} = 0$. In the second step we have defined $\tilde{K}(Z)$ to be given by the same expression, but with the sum restricted to $X \cup P \cup Y \cup (\Lambda - \Lambda') = Z$

Now let Z_{ℓ} be the connected components of Z. We claim that $\tilde{K}(Z) = \prod_{\ell} \tilde{K}(Z_{\ell})$. Since $K_0(X)$ factors over the connected components of X it factors over the $\{Z_{\ell}\}$, and this is true for the entire integrand. Next consider the random walk expansions (159) for $C_{\Lambda}(s), \Gamma_{\Lambda}(s, \tilde{A})$. Since $s_{\Lambda' - Z} = 0$ paths connecting different Z_{ℓ} do not contribute. Hence these operators do not connect different components. Hence the Gaussian integrals factor over the connected components. In each component the measures can be taken as

$$\begin{aligned} d\mu_{\Lambda, Z_{\ell}, s}(A_0) \equiv& d\mu_{[C_{\Lambda}(s)]_{\Lambda \cap Z_{\ell}}, [\alpha_{\Lambda}(s)]_{\Lambda \cap Z_{\ell}}}(A_{0,\Lambda \cap Z_{\ell}}) \\ d\mu_{\Lambda, Z_{\ell}, s}(\Psi_0) \equiv& d\mu_{[\Gamma_{\Lambda}(s,\tilde{A})]_{\Lambda \cap Z_{\ell}}, [\beta_{\Lambda}(s,\tilde{A})]_{\Lambda \cap Z_{\ell}}}(\Psi_{0,\Lambda \cap Z_{\ell}}) \end{aligned} \tag{164}$$

The derivatives and integrals with respect to s_Y preserve the factorization since expressions like $[C_{\Lambda}(s)]_{\Lambda \cap Z_{\ell}}$ only depend on s_Y for $Y \subset Z_{\ell}$. Finally the sum over X, P, Y factorizes as well.

To summarize our expression is

$$\sum_Z \tilde{K}(Z) = \sum_{\{Z_{\ell}\}} \prod_{\ell} \tilde{K}(Z_{\ell}) \tag{165}$$

where the sum is over disjoint connected $\{Z_\ell\}$ intersecting Λ and for any such connected $Z = Z_\ell \neq \emptyset$

$$\tilde{K}(Z) = \sum_{X,P,Y \to Z} \int ds_Y \frac{\partial}{\partial s_Y} [\int K_0(X)\ \chi^*(\Lambda \cap X)\ \zeta^*(P)\ d\mu_{\Lambda,Z,s}(A_0)\ d\mu_{\Lambda,Z,s}(\Psi_0)\ ] \tag{166}$$

Here $X, P, Y \to Z$ means $X \cap \Lambda \neq \emptyset$ (unless $X = \emptyset$) and $P \subset (\Lambda' - X)$ and $Y \subset \Lambda' - (X \cup P)$ and Z is the union of $X \cup P \cup Y$ and any connected components of $\Lambda - \Lambda'$ touching this set. (Or we could write $P \subset (\Lambda' \cap Z - X)$, etc.)

We note the following features:

- In $\tilde{K}(Z)$ all variables are localized in Z.
- If $Z \subset \Lambda'$ then Z contains no part of $\Lambda - \Lambda'$ and so $[\alpha_\Lambda(s)]_Z = [\beta_\Lambda(s, \tilde{A})]_Z = 0$. It follows that in this case $\tilde{K}(Z)$ does not depend on $\Psi_{0,\Lambda^c}, A_{0,\Lambda^c}$.
- We can rule out $X \cup P = \emptyset$ since in this case $Y \neq \emptyset$ and we have $\partial/\partial s_Y[1] = 0$.

part III. We now digress to estimate $\tilde{K}(Z) = \tilde{K}(Z, \tilde{\Psi}(A^+), \Psi, \Psi_{0,\Lambda^c}, \tilde{A}, A, A_{0,\Lambda^c})$ in a series of lemmas. We break the analysis into three parts by writing

$$\begin{aligned} \tilde{K}(Z) &= \sum_{X,P,Y \to Z} \int ds_Y \frac{\partial}{\partial s_Y} F(X, P, s) \\ F(X, P, s) &= \int G(X, s)\ \chi^*(\Lambda \cap X)\ \zeta^*(P)\ \ d\mu_{\Lambda,Z,s}(A_0) \\ G(X, s) &= \int K_0(X)\ \ d\mu_{\Lambda,Z,s}(\Psi_0) \end{aligned} \tag{167}$$

Lemma 6 *The function $G(X, A_0, s)$ is analytic in complex $|A_0(x)| \leq \mathcal{O}(1)p(e_0)$ for $x \in \Lambda$ and satisfies in this domain*

$$\|\frac{\partial}{\partial s_Y} G(X, A_0, s)\|_{h_1} \leq M_0^{-\frac{1}{2}|Y|_1} \prod_\alpha \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X_\alpha|_1)} \tag{168}$$

where $\{X_\alpha\}$ are the connected components of X.

Proof. First we give the bound with $Y = \emptyset$ and A_0 real. The integral be written in more detail as

$$G(X, A_0, s) = \int K_0(X,\ \Psi_0 + [\beta_\Lambda(s, \tilde{A})]_{\Lambda \cap Z},\ A_0)\ d\mu_{[\Gamma_\Lambda(s,\tilde{A})]_{\Lambda \cap Z}}(\Psi_0) \tag{169}$$

We have the bound $|\Gamma_\Lambda(s, \tilde{A}, x, y)| \leq \mathcal{O}(1) exp(-\beta d(x, y))$ uniformly in s. This is proved in lemma 15 in Appendix A for $s = 1$ and the same proof holds for general s. Then

$\|\Gamma_\Lambda(s,\tilde{A})\|^{(1)}$ and $\|\Gamma_\Lambda(s,\tilde{A})\|^{(2)}$ defined in (302) and (310) are bounded uniformly in s. Now we have

$$\begin{aligned}\|G(X,A_0,s)\|_{h_1} \le & \|K_0(X,\ \Psi_0+[\beta_\Lambda(s,\tilde{A})]_{\Lambda\cap Z},\ A_0)\|_{h_1}\\ \le & \|K_0(X,\Psi_0,A_0)\|_{h'}\\ \le & \prod_\alpha \mathcal{O}(e_0 p(e_0))e^{-\mathcal{O}(1)\beta M_1|X_\alpha|_1}\end{aligned} \tag{170}$$

The first estimate follows from lemma 22 in Appendix B and holds provided we chose h_1 so that $\sup_s\|\Gamma_\Lambda(s,\tilde{A})\|^{(2)} \le h_1^2$. The second estimate follows from lemma 20 in Appendix B and holds provided $h_1(1+\sup_s\|\Gamma_\Lambda(s,\tilde{A})[D^{\#}(A^+)]_{\Lambda\Lambda^c}\|^{(1)}) \le h'$, a condition on h'. The last estimate is the bound (153).

The above estimates were carried out for real s_Δ with $|s_\Delta| \le 1$ but we could have allowed complex s_Δ with $|s_\Delta| \le M_0^{\frac{1}{2}}$. In this case we have $|s_\omega| \le M_0^{(\ell(\omega)+1)/2}$ instead of $|s_\omega| \le 1$ but this does not spoil the estimates on $\Gamma_\Lambda(s,\tilde{A})$. In fact $\Gamma_\Lambda(s,\tilde{A})$ is analytic in this domain and so is $G(X,A_0,s)$. The result for $Y \neq \emptyset$ now follows by a Cauchy bound.

The analyticity in A_0 holds for V,W hence for E_0,E_0',K_0 and hence for G. The bounds and analysis are not affected. This completes the proof.

Lemma 7 *The function $F(X,P,s)$ satisfies*

$$\|\frac{\partial}{\partial s_Y}F(X,P,s)\|_{h_0} \le M_0^{-\mathcal{O}(1)|Y|_1}e^{-\mathcal{O}(1)p(e_0)^2|P|_1}\left(\prod_\alpha \mathcal{O}(e_0p(e_0))e^{-\mathcal{O}(1)\beta M_1|X_\alpha|_1}\right) \tag{171}$$

with the first and third $\mathcal{O}(1)$ universal.

Proof. First consider the bound with $Y=\emptyset$. The characteristic function $\chi^*(X)$ ensures that the bounds of the previous lemma are applicable and we have

$$\|F(X,P,s)\|_{h_1} \le \left(\int \zeta^*(P)\ d\mu_{\Lambda,Z,s}(A_0)\right)(\dots) \tag{172}$$

where $(\dots)$ is the parenthetic expression in (171). For $\zeta^*(P)$ we note that for any γ

$$(\chi\left(\frac{|A_0(x)|}{2C_1p(e_0)}\right)-1) \le e^{-16c_1^2\gamma p(e_0)^2+\gamma|A_0(x)|^2}(\chi\left(\frac{|A_0(x)|}{2C_1p(e_0)}\right)-1) \tag{173}$$

We can use this bound at least once in each block of P and obtain

$$|\zeta^*(P)| \le e^{-\mathcal{O}(1)p(e_0)^2|P|_1+\gamma\|A_0\|_P^2} \tag{174}$$

Thus we have the small factors we need and it remains to control

$$\begin{aligned}\int e^{\gamma\|A_0\|_P^2}\ d\mu_{\Lambda,Z,s}(A_0) =& \int e^{\gamma\|A_0+\alpha_\Lambda(s)\|_P^2}d\mu_{C_\Lambda(s)}(A_0)\\ \le & e^{2\gamma\|\alpha_\Lambda(s)\|_P^2}\int e^{2\gamma\|A_0\|_P^2}d\mu_{C_\Lambda(s)}(A_0)\end{aligned} \tag{175}$$

We first estimate $\|\alpha_\Lambda(s)\|^2_P$. As in lemma 15 in Appendix A we have the bound $|C_\Lambda(s,\tilde{A},x,y)| \leq \mathcal{O}(1)exp(-\beta d(x,y))$ uniformly in s. Since we have been careful to separate P by a distance at least $r(e_0)$ from Λ^c we gain a factor $e^{-\frac{1}{2}\beta r(e_0)}$ and thus in

$$\|\alpha_\Lambda(s)\|^2_P \leq \mathcal{O}(e^{-\frac{1}{2}\beta r(e_0)}p(e_0))|P| \tag{176}$$

the dangerous factor $p(e_0)$ from A_0 on $\partial\Lambda$ is controlled. On the other hand for γ sufficiently small

$$\int e^{2\gamma\|A_0\|^2_P} d\mu_{C_\Lambda(s)}(A_0) \ = \det(1-4\gamma\chi_P C_\Lambda(s))^{-\frac{1}{2}} \leq e^{\mathcal{O}(1)\gamma|P|} \tag{177}$$

follows from $\|4\gamma\chi_P C_\Lambda(s)\| \leq \mathcal{O}(1)\gamma$ and $\|4\gamma\chi_P C_\Lambda(s)\|_1 \leq \mathcal{O}(1)\gamma|P|$. Thus we have

$$\int e^{\gamma\|A_0\|^2_P} \ d\mu_{\Lambda,Z,s}(A_0) \leq e^{\mathcal{O}(1)\gamma|P|} \leq e^{\mathcal{O}(1)|P|_1} \tag{178}$$

which can be absorbed by the tiny factor $e^{-\mathcal{O}(1)p(e_0)^2|P|_1}$

Now consider $Y \neq \emptyset$. Unlike the previous lemma we do not have analyticity in s and cannot use a Cauchy bounds. Instead we evaluate the derivatives explicitly. In general a Gaussian integral with covariance $C(s)$ and mean $\alpha(s)$ satisfies

$$\frac{d}{ds}\int f \ d\mu_{C(s),\alpha(s)} = \int (\mathcal{L}'(s)f) \ d\mu_{C(s),\alpha(s)} \tag{179}$$

where $\mathcal{L}(s)$ is the differential operator

$$\mathcal{L}(s) = \frac{1}{2}\sum_{x,y}\frac{\partial}{\partial A_0(x)}C(s,x,y)\frac{\partial}{\partial A_0(y)} + \sum_z \alpha(s,z)\frac{\partial}{\partial A_0(z)} \tag{180}$$

We apply this repeatedly and we also have derivatives acting on G. Altogether we have

$$\begin{aligned}&\frac{\partial}{\partial s_Y}F(X,P,s)\\ =&\sum_{Y_0}\sum_n\sum_{\{Y_1,\dots,Y_n\}}\int\prod_{j=1}^n\left(\frac{\partial\mathcal{L}(s)}{\partial s_{Y_j}}\right)[\frac{\partial G(X,s)}{\partial s_{Y_0}} \ \chi^*(\Lambda\cap X) \ \zeta^*(P)] \ d\mu_{\Lambda,Z,s}(A_0)\end{aligned} \tag{181}$$

where the sum is over subsets $Y_0 \subset Y$ and partitions $\{Y_1,\dots,Y_n\}$ of $Y - Y_0$. Expanding the terms in $\partial\mathcal{L}(s)/\partial s_{Y_j}$ we get a sum over subsets $\mathcal{N}$ of $(1,\dots,n)$ and have

$$\begin{aligned}=&\sum_{Y_0}\sum_n\sum_{\{Y_1,\dots,Y_n\}}\sum_{\mathcal{N}}\sum_{\{x_i,y_j\}_{j\in\mathcal{N}}}\sum_{\{z_j\}_{j\notin\mathcal{N}}}\prod_{j\in\mathcal{N}}\frac{1}{2}\frac{\partial C(s)}{\partial s_{Y_j}}(x_j,y_j)\prod_{j\notin\mathcal{N}}\frac{\partial\alpha_\Lambda(s)}{\partial s_{Y_j}}(z_j)\\ &\int\prod_x\left(\frac{\partial}{\partial A_0(x)}\right)^{n_x}[\frac{\partial G(X,s)}{\partial s_{Y_0}} \ \chi^*(\Lambda\cap X) \ \zeta^*(P)] \quad d\mu_{\Lambda,Z,s}(A_0)\end{aligned} \tag{182}$$

Here n_x is the number of times a variable x occurs in $\{x_i, y_j\}_{j \in \mathcal{N}}$ and $\{z_j\}_{j \notin \mathcal{N}}$. We have $n \leq \sum_x n_x \leq 2n$

We need to estimate the effect of the derivatives with respect to A_0. To begin we have for $n \geq 0$

$$|\left(\frac{\partial}{\partial A_0(x)}\right)^n \chi(\frac{A_0(x)}{2C_1 p(e_0)})| \leq (n!)^2 \left(\frac{\mathcal{O}(1)}{p(e_0)}\right)^n \tag{183}$$

and hence

$$|\prod_x \left(\frac{\partial}{\partial A_0}\right)^{n_x} \chi^*(\Lambda \cap X)| \leq \prod_x (n_x!)^2 \left(\frac{\mathcal{O}(1)}{p(e_0)}\right)^{n_x} \tag{184}$$

One can obtain the same estimate for derivatives of $\zeta^*(P)$. Since derivatives do not enlarge supports we can still extract decay in $|P|_1$ as in (174). Thus we have

$$|\prod_x \left(\frac{\partial}{\partial A_0(x)}\right)^{n_x} \zeta^*(P)| \leq \prod_x [(n_x!)^2 \left(\frac{\mathcal{O}(1)}{p(e_0)}\right)^{n_x}]\ e^{-\mathcal{O}(1)p(e_0)^2|P|_1 + \gamma\|A_0\|_P^2} \tag{185}$$

By the analyticity result of the previous lemma and Cauchy bounds we also have

$$\begin{aligned} &|\prod_x \left(\frac{\partial}{\partial A_0(x)}\right)^{n_x} \frac{\partial G(X,s)}{\partial s_{Y_0}}| \\ &\leq \prod_x [n_x! \left(\frac{\mathcal{O}(1)}{p(e_0)}\right)^{n_x}]\ M_0^{-\frac{1}{2}|Y_0|_1} \prod_\alpha \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X_\alpha|_1)} \end{aligned} \tag{186}$$

We combine the last three results and use some elementary combinatorics to obtain

$$\begin{aligned} &\prod_x \left(\frac{\partial}{\partial A_0(x)}\right)^{n_x} [\frac{\partial G(X,s)}{\partial s_{Y_0}}\ \chi^*(\Lambda \cap X)\ \zeta(P)] \\ &\leq \prod_x [(n_x!)^2] \left(\frac{\mathcal{O}(1)}{p(e_0)}\right)^n e^{\gamma\|A_0\|_P^2} M_0^{-\frac{1}{2}|Y_0|_1} (\dots) \end{aligned} \tag{187}$$

where now $(\dots) = e^{-\mathcal{O}(1)p(e_0)^2|P|_1} \prod_\alpha \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X_\alpha|_1)}$.

Now using the bound of lemma 18 from Appendix A we obtain

$$\begin{aligned} &|\prod_{j \in \mathcal{N}} \frac{\partial C(s)}{\partial s_{Y_j}}(x_j, y_j) \prod_{j \notin \mathcal{N}} \frac{\partial \alpha_\Lambda(s)}{\partial s_{Y_j}}(z_j)| \\ &\leq \prod_{j=1}^n \mathcal{O}(1) M_0^{-\mathcal{O}(1)|Y_j|_1} \prod_{j \in \mathcal{N}} e^{-\beta \mathcal{L}(x_j, y_j, Y_j)} \prod_{j \notin \mathcal{N}} e^{-\mathcal{O}(1)\beta \mathcal{L}(z_j, Y_j)} \end{aligned} \tag{188}$$

where $\mathcal{L}(x, y, Y)$ is the length of the shortest tree through x, y and the centers of the blocks in Y. Here we have used $\exp(-\frac{1}{2}\beta d(Y, \Lambda^c)) \leq \exp(-\frac{1}{2}\beta r(e_0))$ to suppress a factor $p(e_0)$ in $\alpha_\Lambda(s)$. Next since the Y_j associated with a particular x are disjoint one can show that

$$n_x! \leq \mathcal{O}(1)^{n_x} \exp\left(\sum_{j:\ x_j = x} d(x, Y_j)/M_1 + \sum_{j:\ y_j = x} d(x, Y_j)/M_1 + \sum_{j:\ z_j = x} d(x, Y_j)/M_1 \right) \tag{189}$$

(see [19], [7], [16] for similar bounds) and hence

$$\prod_x n_x! \leq (\mathcal{O}(1))^n \exp\left(\sum_{j \in \mathcal{N}} d(x_j, Y_j)/M_1 + \sum_{j \in \mathcal{N}} d(y_j, Y_j)/M_1 + \sum_{j \notin \mathcal{N}} d(z_j, Y_j)/M_1 \right) \tag{190}$$

Even after squaring this factor can be dominated by factors on the right side of (188). Combining (187), (188), (190) we can now bound (182) by

$$\begin{aligned} &\sum_{Y_0} \sum_n \left(\frac{\mathcal{O}(1)}{p(e_0)} \right)^n \sum_{\{Y_1, \dots, Y_n\}} \sum_{\mathcal{N}} \sum_{\{x_i, y_j\}_{j \in \mathcal{N}}} \sum_{\{z_j\}_{j \notin \mathcal{N}}} \\ &\prod_{j=0}^n M_0^{-\mathcal{O}(1)|Y_j|_1} \prod_{j \in \mathcal{N}} e^{-\mathcal{O}(1)\beta \mathcal{L}(x_j, y_j, Y_j)} \prod_{j \notin \mathcal{N}} e^{-\mathcal{O}(1)\beta \mathcal{L}(z_j, Y_j)} \left(\int e^{\gamma \|A_0\|_P^2} \ d\mu_{\Lambda, Z, s}(A_0) \right) (\dots) \end{aligned} \tag{191}$$

We do the sum over x_j, y_j and z_j we get a factor $\prod_j \mathcal{O}(1)|Y_j| e^{-\mathcal{O}(1)\beta\mathcal{L}(Y_j)}$. The $|Y_j|$ can be absorbed by the $M_0^{-\mathcal{O}(1)|Y_j|_1}$. Also we have $\prod_j M_0^{-\mathcal{O}(1)|Y_j|_1} = M_0^{-\mathcal{O}(1)|Y|_1}$. This factor is incorporated into $(\dots)$ which now has the form that we want for the lemma. Nothing depends on $\mathcal{N}$ at this point and the sum gives a factor 2^n. The Gaussian integral is bounded by (178) and the resulting factor absorbed. Thus our expression is bounded by

$$\left[\sum_{Y_0} \sum_n \alpha^n \sum_{\{Y_1, \dots, Y_n\}} \prod_{j=1}^n e^{-\mathcal{O}(1)\beta\mathcal{L}(Y_j)} \right] (\dots) \tag{192}$$

where $\alpha \equiv \mathcal{O}(1) p(e_0)^{-1}$ is small for e_0 small. We dominate the sum over partitions by an unrestricted sum and obtain for the bracketed expression

$$\begin{aligned} [\dots] \leq &\sum_{Y_0} \sum_n \frac{\alpha^n}{n!} \sum_{(Y_1, \dots, Y_n)} \prod_{j=1}^n e^{-\mathcal{O}(1)\beta\mathcal{L}(Y_j)} \\ = &\sum_{Y_0} \exp\left(\alpha \sum_{Y' \subset (Y - Y_0)} e^{-\mathcal{O}(1)\beta\mathcal{L}(Y')} \right) \\ \leq &\sum_{Y_0} e^{\mathcal{O}(1)\alpha|Y - Y_0|_1} \leq 2^{|Y|_1} e^{\mathcal{O}(1)\alpha|Y|_1} \leq e^{|Y|_1} \end{aligned} \tag{193}$$

The second inequality is standard. The sum here is over Y' which are not connected we definitely need the stronger $e^{-\mathcal{O}(1)\beta\mathcal{L}(Y')}$ decay. Finally the factor $e^{|Y|_1}$ is absorbed by the $M_0^{-\mathcal{O}(1)|Y|_1}$ in $(\dots)$ to complete the proof.

Lemma 8 *For any $\kappa > 0$, Z connected, and $Z \cap \Lambda \neq \emptyset$ we have under the hypotheses of the theorem*

$$\|\tilde{K}(Z)\|_{h_1} \leq \mathcal{O}(e_0 p(e_0)) e^{|Z\cap(\Lambda-\Lambda')|_1} e^{-\kappa|Z-(\Lambda-\Lambda')|_1} \tag{194}$$

Remark. If $Z \subset \Lambda'$ this becomes

$$\|\tilde{K}(Z)\|_{h_1} \leq \mathcal{O}(e_0 p(e_0)) e^{-\kappa|Z|_1} \tag{195}$$

Proof. Assuming $M_0, M_1, p(e_0)$ are sufficiently large we have by the previous lemma

$$\begin{aligned}
\|\tilde{K}(Z)\|_{h_1} \leq & \sum_{X,P,Y \to Z} M_0^{-\mathcal{O}(1)|Y|_1} e^{-\mathcal{O}(1)p(e_0)^2|P|_1} \left(\prod_\alpha \mathcal{O}(e_0 p(e_0)) e^{-\mathcal{O}(1)\beta M_1 |X_\alpha|_1} \right) \\
\leq & \sum_{X,P,Y \to Z} \left(\prod_\alpha e^{-3\kappa|X_\alpha|_1} \right) e^{-3\kappa|P|_1} e^{-3\kappa|Y|_1} \\
\leq & e^{-2\kappa|Z-(\Lambda-\Lambda')|_1} \left(\sum_{X \subset Z, X_\alpha \cap \Lambda \neq \emptyset} \prod_\alpha e^{-\kappa|X_\alpha|_1} \right) \Big(\sum_{P \subset Z \cap \Lambda'} e^{-\kappa|P|_1} \Big) \Big(\sum_{Y \subset Z \cap \Lambda'} e^{-\kappa|Y|_1} \Big) \\
\leq & e^{-2\kappa|Z-(\Lambda-\Lambda')|_1} e^{|Z\cap\Lambda|_1} e^{2|Z\cap\Lambda'|_1} \\
\leq & e^{-\kappa|Z-(\Lambda-\Lambda')|_1} e^{|Z\cap(\Lambda-\Lambda')|_1}
\end{aligned} \tag{196}$$

In the third inequality we use that X, P, Y are disjoint and $X \cup P \cup Y \supset (Z - (\Lambda - \Lambda'))$ and in the last inequality we use $(Z - (\Lambda - \Lambda')) \supset Z \cap \Lambda'$. Since it is not possible that $X \cup P = \emptyset$ we can also extract the factor $\mathcal{O}(e_0 p(e_0))$ from either the X-terms or the P terms. This completes the proof of the lemma.

part IV: Now we return to the proof of the theorem. At this point we have the expression

$$\exp\left(\sum_{X : X \subset \Lambda^c} E_0'(X) \right) \sum_{\{Z_\ell\} : Z_\ell \cap \Lambda \neq \emptyset} \prod_\ell \tilde{K}(Z_\ell) \tag{197}$$

For each collection $\{Z_\ell\}$ with $Z_\ell \cap \Lambda \neq \emptyset$ consider the $\{Z_\ell\}$ touching $(\Lambda')^c$. Take the union of $(\Lambda')^c$ and the $\{Z_\ell\}$ touching $(\Lambda')^c$, add a corridor of M_1-blocks and call this the Θ^c, written $\{Z_\ell\} \to \Theta^c$. (So $(\Lambda')^c \subset \Theta^c$ and $\Theta \subset \Lambda'$). We classify the terms in the sum by the Θ that they determine. The remaining $\{Z_\ell\}$ are in Θ and are otherwise unrestricted. Thus the second factor in (197) can be written

$$\sum_{\Theta\subset\Lambda'}\sum_{\{Z_\ell\}\to\Theta^c}\prod_\ell \tilde{K}(Z_\ell)\left(\sum_{\{Z'_\ell\}:Z'_\ell\subset\Theta}\prod_\ell \tilde{K}(Z'_\ell)\right) \tag{198}$$

and (197) itself can be written

$$\sum_{\Theta\subset\Lambda'}\mathcal{T}(\Theta^c)\left(\sum_{\{Z'_\ell\}:Z'_\ell\subset\Theta}\prod_\ell \tilde{K}(Z'_\ell)\right) \tag{199}$$

where

$$\mathcal{T}(\Theta^c)=\exp(\sum_{X:X\subset\Lambda^c}E'_0(X))\sum_{\{Z_\ell\}\to\Theta^c}\prod_\ell \tilde{K}(Z_\ell) \tag{200}$$

Let $\{\Theta^c_\beta\}$ be the connected components of Θ . The sum over $\{Z_\ell\}$ factors over $\{\Theta^c_\beta\}$ as do the terms in $\sum_{X:X\subset\Lambda^c}E_0(X)$ since the X must be connected and so lie in a single connected component of Λ^c. Thus we get $\mathcal{T}(\Theta^c_\beta)=\prod_\beta\mathcal{T}(\Theta^c_\beta)$ where

$$\mathcal{T}(\Theta^c_\beta)=\exp\left(\sum_{X:X\subset\Theta^c_\beta\cap\Lambda^c}E'_0(X)\right)\sum_{\{Z_\ell\}\to\Theta^c_\beta}\prod_\ell \tilde{K}(Z_\ell) \tag{201}$$

Lemma 9

$$\|\mathcal{T}(\Theta^c_\beta)\|_{h_1}\leq e^{\mathcal{O}(1)|\Theta^c_\beta-\Lambda'|_1}e^{-\kappa|\Theta^c_\beta\cap\Lambda'|_1} \tag{202}$$

Proof. Using the estimates (146) and (195) we have

$$\|\mathcal{T}(\Theta^c_\beta)\|_{h_1}\leq e^{\mathcal{O}(e_0p(e_0))|\Theta^c_\beta\cap\Lambda^c|}\sum_{\{Z_\ell\}\to\Theta^c_\beta}\prod_\ell\mathcal{O}(e_0p(e_0))e^{|Z_\ell\cap(\Lambda-\Lambda')|_1}e^{-2\kappa|Z_\ell-(\Lambda-\Lambda')|_1} \tag{203}$$

The first factor is less than $e^{\mathcal{O}(1)|\Theta^c_\beta-\Lambda'|_1}$. Now a factor $e^{-\kappa|Z_\ell-(\Lambda-\Lambda')|_1}$ is less than $e^{-\kappa|Z_\ell\cap\Lambda'|_1}$ and after the product over ℓ this gives the $e^{-\kappa|\Theta^c_\beta\cap\Lambda'|_1}$ which is the decay factor we want. The other factor satisfies $e^{-\kappa|Z_\ell-(\Lambda-\Lambda')|_1}\leq e^{-\kappa|Z_\ell|}e^{\kappa|Z_\ell\cap(\Lambda-\Lambda')|_1}$. Then we use $\prod_\ell e^{(\kappa+1)|Z_\ell\cap(\Lambda-\Lambda')|_1}=e^{(\kappa+1)|\Theta^c_\beta\cap(\Lambda-\Lambda')|_1}$ and this is less than $e^{\mathcal{O}(1)|\Theta^c_\beta-\Lambda'|_1}$. We are left with the sum

$$\sum_{\{Z_\ell\}\to\Theta^c_\beta}\prod_\ell\mathcal{O}(e_0p(e_0))e^{-\kappa|Z_\ell|_1}\leq\exp(\mathcal{O}(e_0p(e_0))|\Theta^c_\beta-\Lambda'|_1) \tag{204}$$

For this estimate we enlarge the sum to Z_ℓ touching $\Theta^c_\beta-\Lambda'$ and identify an exponential as in (154). This completes the proof.

part V: This bound on $\tilde{K}$ in Θ is sufficiently small that we can exponentiate the expression in parentheses in (199). See [24], [7] for more details of this standard argument. We first write

$$\sum_{\{Z_\ell\}:Z_\ell\subset\Theta}\prod_\ell \tilde{K}(Z_\ell) = 1+\sum_{n=1}^\infty \frac{1}{n!}\sum_{(Z_1,\dots,Z_n)}\{\prod_{i<j}\zeta(Z_i,Z_j)\}\tilde{K}(Z_1)\dots\tilde{K}(Z_n) \tag{205}$$

where the sum over $(Z_1,\dots,Z_n)$ is now unrestricted, but $\zeta(Z_i,Z_j)=0$ if the sets touch and $\zeta(Z_i,Z_j)=1$ if they do not. This can be rearranged as

$$\sum_{\{Z_\ell\}:Z_\ell\subset\Theta}\prod_\ell \tilde{K}(Z_\ell) = \exp(\sum_{X\subset\Theta}\tilde{E}(X)) \tag{206}$$

where

$$\tilde{E}(X)=\sum_{n=1}^\infty \frac{1}{n!}\sum_{\substack{Z_1,\dots,Z_n\\ \cup_i Z_i = X}}\rho^T(Z_1,...,Z_n)\tilde{K}(Z_1)\dots\tilde{K}(Z_n) \tag{207}$$

and where

$$\rho^T(Z_1,...,Z_n)=\sum_G\prod_{\{i,j\}\in G}(\zeta(Z_i,Z_j)-1) \tag{208}$$

Here G runs over the connected graphs on $(1,...,n)$.

One can use the bound (195) on $\tilde{K}$ and a tree domination argument to show

$$\|\tilde{E}(X)\|_{h_1}\leq \mathcal{O}(e_0p(e_0))e^{-\kappa|X|_1} \tag{209}$$

This completes the proof of the theorem.

4.4 more adjustments

We make adjustments which will simplify the treatment of perturbation theory in the small field region.

We first want to resum the expression in the small field region. Accordingly we define for any $\Theta\subset\Lambda'$

$$Z^\dagger_\Theta = \int \exp\left(\sum_{X\subset\Theta}E_0'(X)\right)\chi^*(\Theta,A_0)\ d\mu_{C(1,\Theta)}(A_0)\ d\mu_{\Gamma(1,\Theta,\tilde{A})}(\Psi_0) \tag{210}$$

where for $x,y\in\Theta$

$$C(s,\Theta,x,y)=\sum_{\substack{\omega:x\to y\\ \bar{\omega}\subset\Theta}} s_\omega\ C_\omega(x,y) \tag{211}$$

Here $\bar{\omega}$ is the localization of ω defined in Appendix A. This is positive definite. There is a similar expression for $\Gamma(s,\Theta,\tilde{A})$. If we repeat the steps of theorem 1 we find that

$$Z^\dagger_\Theta = \sum_{\{Z_\ell\}:Z_\ell\subset\Theta}\prod_\ell K^\dagger(Z_\ell)=\exp(\sum_{X\subset\Theta}E^\dagger(X)) \tag{212}$$

where $E^{\dagger}(X)$ is defined from $K^{\dagger}(Z)$ by (207), where

$$K^{\dagger}(Z) = \sum_{X,P,Y \to Z} \int ds_Y \frac{\partial}{\partial s_Y}[\int K_0(X)\ \chi^*(X)\ \zeta^*(P) d\mu_{C(s,\Theta)}(A_0)\ d\mu_{\Gamma(s,\Theta,\tilde{A})}(\Psi_0)] \tag{213}$$

and where K_0 is still defined by (152). The sum is over disjoint X, P, Y whose union is Z. We could as well write $C(s,Z)$ and $\Gamma(s,Z,\tilde{A})$ for the covariances.

The expression for $K^{\dagger}(Z)$ is identical with the expression for $\tilde{K}(Z)$ specialized to the case $Z \subset \Lambda'$. Indeed the measures have mean zero and the same covariance, [5] and the restrictions on the sums are the same. Hence also for $X \subset \Theta$ we have $E^{\dagger}(X) = \tilde{E}(X)$ and so we have the resummation

$$\exp(\sum_{X \subset \Theta} \tilde{E}(X)) = Z^{\dagger}_{\Theta} \tag{214}$$

Next we work toward a more translation invariant expression which means eliminating dependence on Ω, Λ, Θ. We first work on the measure and define

$$Z^{\#}_{\Theta} = \int \exp\left(\sum_{X \subset \Theta} E'_0(X)\right) \chi^*(\Theta, A_0)\ d\mu_{C^{loc}}(A_0)\ d\mu_{\Gamma^{loc}(\tilde{A})}(\Psi_0) \tag{215}$$

Now C^{loc} is a small perturbation of C^* and hence is positive definite. Thus the expression is well-defined.

Lemma 10

$$Z^{\#}_{\Theta} = \sum_{\{Z_\ell\}: Z_\ell \cap \Theta \neq \emptyset} \prod_{\ell} K^{\#}(Z_\ell) = \exp(\sum_{X \cap \Theta \neq \emptyset} E^{\#}(X)) \tag{216}$$

where $K^{\#}, E^{\#}$ satisfy the same bounds (195),(209) as $\tilde{K}, \tilde{E}$.

Proof. This is another cluster expansion which follows the steps in Theorem 1 with some differences. C^{loc} still has a broken version $C^{loc}(s)$ which is also a small perturbation of C^* and positive definite. However since there is no boundary for C^{loc} we now vary s_Δ for all Δ in $(X \cup P)^c$, not just $\Theta - (X \cup P)$. We get polymer activities $K^{\#}(Z)$ for any connected Z intersecting Θ given by

$$K^{\#}(Z) = \sum_{X,P,Y \to Z} \int ds_Y \frac{\partial}{\partial s_Y}[\int K_0(X)\ \chi^*(X)\ \zeta^*(P) d\mu_{C^{loc}(s)}(A_0)\ d\mu_{\Gamma^{loc}(s,\tilde{A})}(\Psi_0)] \tag{217}$$

where $X \subset \Theta$, $P \subset \Theta - X$, $Y \subset (X \cup P)^c$, and $Z = X \cup P \cup Y$. This is bounded as before and the exponential version follows as before. This completes the proof.

---

[5] When $Z \subset \Lambda'$ and $s_\Delta = 0$ for Δ around Z we have $[C_\Lambda(s)]_Z = C(s,Z)$.

Now we compare $\mathcal{Z}^{\dagger}_{\Theta}, \mathcal{Z}^{\#}_{\Theta}$. Recall that Θ is a union of M_1-blocks. Take the R_0 blocks contained in Θ, delete an R_0 corridor, and call the result Θ'. Deleting another corridor gives Θ''.

Lemma 11

$$\mathcal{Z}^{\dagger}_{\Theta} = \mathcal{Z}^{\#}_{\Theta} \exp\left(\sum_{X \subset (\Theta'')^c, X\cap\Theta \neq \emptyset} B^{\#}(X) + \sum_{X \cap \Theta'' \neq \emptyset} R^{\#}(X) \right) \tag{218}$$

where

$$\begin{aligned} \|B^{\#}(X)\|_{h_1} \leq & \mathcal{O}(e_0 p(e_0)) e^{-\kappa |X|_1} \\ \|R^{\#}(X)\|_{h_1} \leq & \mathcal{O}(e^{-r(e_0)/M_1}) e^{-\frac{1}{2}\kappa |X|_1} \end{aligned} \tag{219}$$

Proof. We have

$$\mathcal{Z}^{\dagger}_{\Theta} = \mathcal{Z}^{\#}_{\Theta} \exp\left(\sum_{X\cap\Theta\neq\emptyset} (E^{\dagger}(X) - E^{\#}(X)) \right) \tag{220}$$

with the convention that $E^{\dagger}(X) = 0$ unless $X \subset \Theta$. Define $B^{\#}(X)$ and $R^{\#}(X)$ to be the expression $E^{\dagger}(X) - E^{\#}(X)$ when respectively $X \subset (\Theta'')^c$ and when X intersects Θ''. The bound on $B^{\#}$ follows from the separate bounds on $E^{\dagger}(X), E^{\#}(X)$. To bound $R^{\#}$ first suppose that X also intersects $(\Theta')^c$. Then $M_1|X|_1 \geq r(e_0)$ and we use $e^{-\frac{1}{2}\kappa|X|_1} \leq e^{-r(e_0)/M_1}$ in each term to obtain the bound. It remains to consider $R^{\#}(X)$ when $X \subset \Theta'$ and now we really look at the difference.

We interpolate between $C(1,\Theta)$ and C^{loc}. with

$$C(u) = u\ C(1,\Theta) + (1-u)\ C^{loc} \tag{221}$$

which is also positive definite. Together with a similar $\Gamma(u,\tilde{A})$ we define $Z_{\Theta}(u)$. There are also broken versions $C(u,s) = u\ C(s,\Theta) + (1-u)\ C^{loc}(s)$ and $\Gamma(u,s,\tilde{A})$ which we use to expand $Z_{\Theta}(u)$ in terms of

$$K(u,Z) = \sum_{X,P,Y\to Z} \int ds_Y \frac{\partial}{\partial s_Y}[\int K_0(X)\ \chi^*(X)\ \zeta^*(P) d\mu_{C(u,s)}(A_0)\ d\mu_{\Gamma(u,s,\tilde{A})}(\Psi_0)] \tag{222}$$

and associated $E(u,X)$. We follow the setup of the previous lemma so Z is only required to intersect Θ. However $K(1,Z)$ is only non-zero if $Z \subset \Theta$.

The derivative with respect to u satisfies

$$\begin{aligned} &\frac{d}{du}K(u,Z) = \sum_{X,P,Y\to Z} \int ds_Y \frac{\partial}{\partial s_Y} \\ &\{\int d\mu_{C(u,s)}(A_0)\ \chi^*(X)\ \zeta^*(P) \frac{\partial}{\partial u}[\int K_0(X)\ d\mu_{\Gamma(u,s,\tilde{A})}(\Psi_0)] \\ &+ \frac{\partial}{\partial u'} \int d\mu_{C(u',s)}(A_0)\ \chi^*(X)\ \zeta^*(P)[\int K_0(X)\ d\mu_{\Gamma(u,s,\tilde{A})}(\Psi_0)]_{u'=u}\} \end{aligned} \tag{223}$$

To estimate this expression for $Z \subset \Theta'$ we look at $\partial C(u,s)/\partial u = C(s,\Theta) - C^{loc}(s)$. We use that for $x, y \in \Theta'$

$$|C(s,\Theta,x,y) - C^{loc}(s,x,y)| \leq \mathcal{O}(e^{-\beta r(e_0)})e^{-\beta d(x,y)} \tag{224}$$

To see this compare each term to $C(s,x,y)$ and notice that only paths of length greater than $r(e_0)$ contribute. There is a similar bound for $\Gamma(s,\Theta,\tilde{A},x,y) - \Gamma^{loc}(s,\tilde{A},x,y)$

Because of the Γ bound the expression $\int K_0(X)d\mu_{\Gamma(u,s)}$ in the first term in (223) is analytic in $|u| \leq e^{\mathcal{O}(1)\beta r(e_0)}$. By a Cauchy bound the derivative in u gives a factor $e^{-\mathcal{O}(1)\beta r(e_0)}$ The rest of the estimate proceeds as in theorem 1 and we have the bound $e^{-\mathcal{O}(1)\beta r(e_0)}e^{-\kappa|Z|_1}$. For the second term in (223) the derivative with respect to u' is evaluated using the identity (179). This introduces $\partial C(u,s)/\partial u$ gives us the factor $e^{-\beta r(e_0)}$, even when derivatives with respect to s are piled onto it. Again the estimate proceeds as in theorem 1 with the same result. Altogether then we have for $Z \subset \Theta'$

$$\|\frac{d}{du}K(u,Z)\|_{h_1} \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)})e^{-\kappa|Z|_1} \tag{225}$$

This leads to the bound for $X \subset \Theta'$

$$\|\frac{d}{du}E(u,X)\|_{h_1} \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)})e^{-\kappa|X|_1} \tag{226}$$

and the same bound now holds for

$$E^{\dagger}(X) - E^{\#}(X) = E(1,X) - E(0,X) = \int_0^1 \frac{d}{du}E(u,X)\ du \tag{227}$$

This is the bound on $R^{\#}(X)$ for $X \subset \Theta'$, it is stronger than we need, and the proof is complete.

Now we work on $Z^{\#}_{\Theta}$. We recall that in $\Theta \subset \Lambda'$ we have $E'_0(X) = -V^*_0(X) + R_0(X)$ where $R_0(X)$ still has some Ω, Λ-dependence but is tiny. We drop this term and define

$$Z^*_{\Theta} = \int \exp\left(\sum_{X\subset\Theta} -V^*_0(X)\right) \chi^*(\Theta, A_0)\ d\mu_{C^{loc}}(A_0)\ d\mu_{\Gamma^{loc}(\tilde{A})}(\Psi_0) \tag{228}$$

As before follow theorem 1 and obtain

$$Z^*_{\Theta} = \sum_{\{Z_\ell\}:Z_\ell\cap\Theta\neq\emptyset} \prod_\ell K^*(Z_\ell) = \exp(\sum_{X\cap\Theta\neq\emptyset} E^*(X)) \tag{229}$$

again with $\|E^*(x)\|_{h_1} \leq \mathcal{O}(e_0 p(e_0))e^{-\kappa|X|_1}$.

Lemma 12

$$\mathcal{Z}^{\#}_{\Theta} = \mathcal{Z}^*_{\Theta} \exp\left(\sum_{X\cap\Theta\neq\emptyset} R^*(X)\right) \tag{230}$$

where

$$\|R^*(X)\|_{h_1} \leq \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)})e^{-\kappa|X|_1} \tag{231}$$

Proof. The proof is similar to the previous lemma, but easier. The formula holds with $R^*(X) = E^{\#}(X) - E^*(X)$ so it suffices to establish the bound for this object. To interpolate between $V_0^*(X)$ and $E_0'(X)$ we introduce $E_0(u,X) = -V_0^*(X) + uR_0(X)$. This defines $K_0(u,X)$ by (152) and then

$$K(u,Z) = \sum_{X,P,Y \to Z} \int ds_Y \frac{\partial}{\partial s_Y} [\int K_0(u,X)\ \chi^*(X)\ \zeta^*(P) d\mu_{C^{loc}(s)}(A_0)\ d\mu_{\Gamma^{loc}(s,\tilde{A})}(\Psi_0)] \tag{232}$$

and from this $E(u,X)$. Since $\|R_0(X)\|_{h'}$ satisfies the bound (146) we have that $E_0(u,X)$ is analytic in $|u| \leq \mathcal{O}(e^{\mathcal{O}(1)\beta r(e_0)})$ and the same holds for $K_0(u,X), K(u,Z), E(u,X)$. Now from the bound $\|E(u,X)\|_{h_1} \leq \mathcal{O}(e_0 p(e_0)) e^{-\kappa|X|_1}$ and a Cauchy bound we obtain

$$\|\frac{d}{du} E(u,X)\|_{h_1} \leq\ \mathcal{O}(e^{-\mathcal{O}(1)\beta r(e_0)}) e^{-\kappa|X|_1} \tag{233}$$

and the result now follows from

$$E^{\#}(X) - E^*(X) = E(1,X) - E(0,X) = \int_0^1 \frac{d}{du} E(u,X)\ du \tag{234}$$

Remarks.

1. $E^*(X) = E^*(X, \tilde{\Psi}(\tilde{A}), \tilde{A})$ only depends on the indicated variables in X (and in fact on $\tilde{\Psi}(\tilde{A})$ only in $X \cap \Theta$). We can also consider the kernel norm of $E^*(X)$ as defined in (55). We claim that in the kernel norm we have the same bound:

$$|E^*(X)|_{h_1} \leq \mathcal{O}(e_0 p(e_0)) e^{-\kappa|X|_1} \tag{235}$$

   This follows by repeating the analysis of theorem 1 working with a mixed norm which is kernel in the external variable $\tilde{\Psi}(\tilde{A})$ and standard in the fluctuation variable Ψ_0. This bound will have better iteration properties.

2. $E^*(X)$ is translation covariant. If $X \subset \Theta$ the Θ dependence drops out of the definition of $E^*(X)$. Hence if $X, X + a \subset \Theta$ one can show

$$E^*(X + a, \tilde{\Psi}(\tilde{A})(\cdot - a), \tilde{A}(\cdot - a)) = E^*(X, \tilde{\Psi}(\tilde{A}), \tilde{A}) \tag{236}$$

   Here we use the translation covariance of $V_0^*(X)$ and C^{loc}, Γ^{loc}.

4.5 perturbation theory

We study the perturbation theory for $\mathcal{Z}^*_{\Theta}$ defined in (228). In this expression we have the potential $\sum_{X\subset\Theta} V^*_0(X) \equiv V^*_{\Theta}$. This is essentially the original potential restricted to Θ and is given explicitly by

$$\begin{aligned} V^*_{\Theta}(\tilde\Psi(\tilde A),\Psi_0,\tilde A,A_0) =&|M(\tilde A)\tilde\Psi(\tilde A) - Q_{e_0}(\tilde A + A_0)[\tilde\Psi(\tilde A)+\Psi_0]_{\Theta}|^2 - \{A_0 = 0\} \\ &+\Big([\bar{\tilde\Psi}(\tilde A)+\bar\Psi_0]_{\Theta}, D_{e_0}(\tilde A + A_0)[\tilde\Psi(\tilde A)+\Psi_0]_{\Theta}\Big) - \{A_0=0\} \\ &+\sum_{x\in\Theta} :[\bar{\tilde\Psi}(\tilde A)+\bar\Psi_0](x)\delta m_0[\tilde\Psi(\tilde A)+\Psi_0](x):_{\hat S_0} + \delta\mathcal{E}_0|\Theta| \\ \equiv& V^{**}_{\Theta}(\tilde\Psi(\tilde A),\Psi_0,\tilde A,A_0) + \delta V_{\Theta}(\tilde\Psi(\tilde A),\Psi_0,) \end{aligned} \tag{237}$$

where $M(\tilde A)$ is defined in (141) (without the restriction to Λ which is not needed here).

For our perturbation expansion we introduce

$$V(t) = V^{**}_{\Theta}(\tilde\Psi(\tilde A),\Psi_0,\tilde A,tA_0) + t^2\delta V_{\Theta}(\tilde\Psi(\tilde A),\Psi_0,) \tag{238}$$

so that $V(1) = V^*_{\Theta}$ and $V(0)=0$. We also define for $0\leq t\leq 1$

$$Z(t) = \int \exp\left(-V(t)\right)\chi^*(\Theta,A_0)\ d\mu_{C^{loc}}(A_0)\ d\mu_{\Gamma^{loc}(\tilde A)}(\Psi_0) \tag{239}$$

and then $Z(1) = Z^*_{\Theta}$. If we restore a local expansion for $V(t)$ we can just as for Z^*_{Θ} obtain a local expansion

$$\mathcal{Z}(t) = \exp\left(\sum_{X\cap\Theta\neq\emptyset} E(t,X)\right) \tag{240}$$

and $E(t,X)$ satisfies the same bounds as $E^*(X) = E(1,X)$ uniformly in t.

Our perturbation theory is the expansion $\log\mathcal{Z}(t)$ around $t=0$ evaluated at $t=1$. We are especially interested in second order. At first instead of $\mathcal{Z}(t)$ let us consider $\tilde{\mathcal{Z}}(t)$ defined just as $\mathcal{Z}(t)$ but with the characteristic function omitted. Computing some Gaussian integrals we find:

$$
\begin{aligned}
P_\Theta(\tilde{\Psi}(\tilde{A}),\tilde{A}) \equiv & \frac{1}{2}(\log \tilde{\mathcal{Z}})''(0) \\
=&\frac{1}{2}\int \Big(V'(0)^2 - V''(0)\Big) \quad d\mu_{C^{loc}}(A_0)\ d\mu_{\Gamma^{loc}(\tilde{A})}(\Psi_0) \\
=&\frac{1}{2}\sum_{x,y\in\Theta} J^{(1)}_\mu(x)C^{loc}(x,y)J^{(1)}_\mu(y) - \frac{1}{2}\sum_{x\in\Theta} J^{(2)}_{\mu,\mu}(x,x)C^{loc}(x,x) \\
+&\frac{1}{2}\sum_{x,y,z,w\in\Theta} \bar{K}^{(1)}_\mu(z,x)\Gamma^{loc}(\tilde{A};z,w)K^{(1)}_\mu(w,y)\ C^{loc}(x,y) \\
-&\frac{1}{2}\sum_{x,y,z,w\in\Theta} K^{(1)}_\mu(z,x)\Gamma^{loc}(\tilde{A};z,w)\bar{K}^{(1)}_\mu(w,y)\ C^{loc}(x,y) \\
-&\sum_{\substack{x,y,z,z'\\ w,w'\in\Theta}} tr\left(L^{(1)}_\mu(z,z',x)\Gamma^{loc}(\tilde{A};z',w')L^{(1)}_\mu(w',w,y)\Gamma^{loc}(\tilde{A};w,z)\right) C^{loc}(x,y) \\
-&\frac{1}{2}\sum_{x,z,z'\in\Theta} tr\left(L^{(2)}_\mu(z,z',x,x)\Gamma^{loc}(\tilde{A};z',z)\right) C^{loc}(x,x) \\
-&\sum_{x\in\Theta} :\bar{\tilde{\Psi}}(\tilde{A},x)\delta m_0\tilde{\Psi}(\tilde{A},x):_{\hat{S}_0-\Gamma^{loc}(\tilde{A})} - \delta\mathcal{E}_0|\Theta|
\end{aligned}
\tag{241}
$$

These correspond to the diagrams of figure 2 (except the counterterms). The vertex functions are

$$
\begin{aligned}
J^{(n)}_{\mu_1,\dots,\mu_n}(x_1,\dots,x_n,\tilde{\Psi}(\tilde{A}),\tilde{A}) &= \frac{\partial^n V^{**}_\Theta}{\partial A_{0,\mu_1}(x_1)\dots\partial A_{0,\mu_n}(x_n)}(\tilde{\Psi}(\tilde{A}),0,\tilde{A},0) \\
\bar{K}^{(n)}_{\mu_1,\dots,\mu_n}(z,x_1,\dots,x_n,\tilde{\Psi}(\tilde{A}),\tilde{A}) &= \frac{\partial^{n+1} V^{**}_\Theta}{\partial \Psi_{0,}(z)\partial A_{0,\mu_1}(x_1)\dots\partial A_{0,\mu_n}(x_n)}(\tilde{\Psi}(\tilde{A}),0,\tilde{A},0) \\
\bar{L}^{(n)}_{\mu_1,\dots,\mu_n}(z,z',x_1,\dots,x_n,\tilde{\Psi}(\tilde{A}),\tilde{A})& \\
= \frac{\partial^{n+2} V^{**}_\Theta}{\partial \bar{\Psi}_0(z)\partial\Psi_0(z')\partial A_{0,\mu_1}(x_1)\dots\partial A_{0,\mu_n}(x_n)}&(\tilde{\Psi}(\tilde{A}),0,\tilde{A},0)
\end{aligned}
\tag{242}
$$

and K has $\partial/\partial\bar{\Psi}_0$ instead of $\partial/\partial\Psi_0$. These vanish unless $x_1 = \dots = x_n$ and $\mu_1 = \dots = \mu_n$. They are independent of Θ away from the boundary.

This differs somewhat from the standard lattice perturbation theory. There are are no external photon lines corresponding to the photon field $\tilde{A}$. Instead $\tilde{A}$ appears as a background field in the propagators and vertices. Another difference is that the vertices are not entirely pointlike due to the presence of Q terms in V^{**}_Θ

With this preliminary calculation out of the way we are now ready to state:

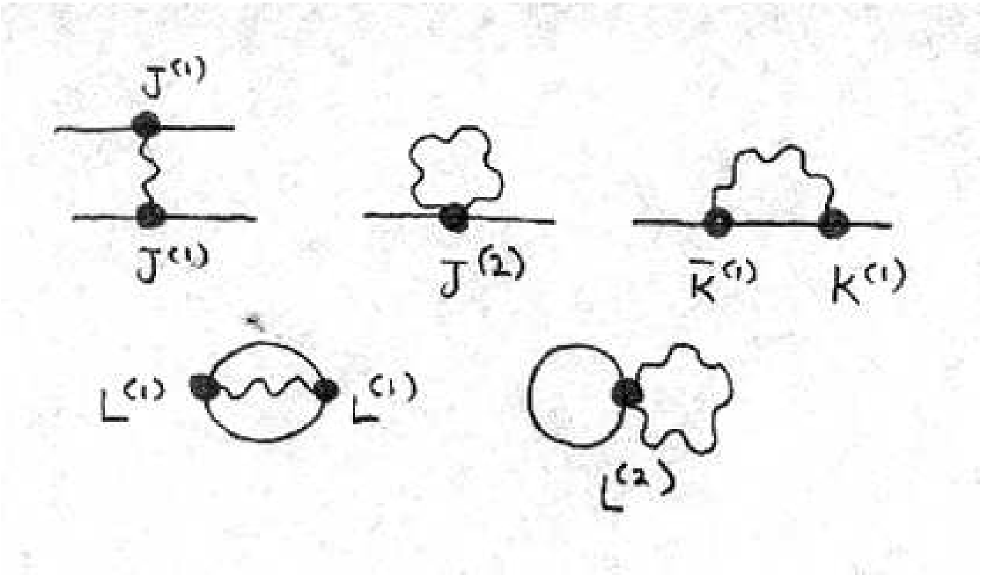

Figure 2: second order perturbation theory

Theorem 2

$$\mathcal{Z}^*_\Theta = \exp\left(P_\Theta + \sum_{X\cap\Theta\neq\emptyset} E^{**}(X)\right) \tag{243}$$

The functions $E^{**}(X)$ are translation covariant inside Θ and for any $\epsilon > 0$ we have

$$\|E^{**}(X)\|_{h_1} \leq \mathcal{O}(e_0^{4-\epsilon})e^{-\kappa|X|_1} \tag{244}$$

also in the kernel norm.

Proof. We expand $\log \mathcal{Z}^*_\Theta = \log \mathcal{Z}(1)$ by

$$\log \mathcal{Z}(1) = \log \mathcal{Z}(0) + \frac{1}{2!}(\log \mathcal{Z})''(0) + +\frac{1}{3!}\int_0^1 (1-t)^3 (\log \mathcal{Z})''''(t)dt \tag{245}$$

To treat the remainder term we use the expansion $\log \mathcal{Z}(t) = \sum_X E(t,X)$ from (240). This gives a contribution $\frac{1}{3!}\int_0^1 (1-t)^3 E''''(t,X)dt$ to $E^{**}(X)$. To analyze this term we first claim $E(t,X)$ is actually analytic in complex $|t| \leq e_0^{-1+\epsilon}$ with a weaker bound. This follows because t enters V(t) either in the combination $e^{ite_0A_0} - 1$ for the main terms or t^2e_0 for the counterterms. In the first case we have our characteristic function enforcing that $|A_0| \leq \mathcal{O}(p(e_0))$ and thus this factor is $\mathcal{O}(e_0^\epsilon p(e_0))$. The counterterms are $\mathcal{O}(e_0^{2\epsilon})$. Altogether we have that $V(t)$ is $\mathcal{O}(e_0^\epsilon p(e_0))$. This carries through the proof of theorem 1 and yields $\|E(t,X)\|_{h_1} \leq \mathcal{O}(e_0^\epsilon p(e_0)e^{-\kappa|X|_1})$ for $|t| \leq e_0^{-1+\epsilon}$ Now returning to $0 \leq t \leq 1$ and using a Cauchy bound we have for the fourth derivative

$\|E''''(t,X)\|_{h_1} \leq \mathcal{O}(e_0^{4-3\epsilon} p(e_0) e^{-\kappa|X|_1})$. Since $p(e_0) \leq e_0^{-\epsilon}$ and ϵ is arbitrary we can take this to be $\mathcal{O}(e_0^{4-\epsilon} e^{-\kappa|X|_1})$ as claimed.

Next consider the second order term. This time we do not use (240) but instead use the global representation (239). Thus we almost get the terms we computed in (241), but now we must deal with the characteristic functions. We compute

$$\frac{1}{2}(\log \mathcal{Z})''(0) = \frac{1}{2} \frac{\int (V'(0)^2 - V''(0))\, \chi^*(\Theta, A_0)\; d\mu_{C^{loc}}(A_0)\; d\mu_{\Gamma^{loc}(\tilde{A})}(\Psi_0)}{\int \chi^*(\Theta, A_0)\; d\mu_{C^{loc}}(A_0)} \tag{246}$$

The four-fermion part of this is

$$\frac{1}{2} \sum_{x,y \in \Theta} J_\mu^{(1)}(x) J_\mu^{(1)}(y) C_\chi^{loc}(x,y) \tag{247}$$

where (no sum on μ)

$$C_\chi^{loc}(x,y) = \frac{\int A_{\mu,0}(x) A_{\mu,0}(y) \chi^*(\Theta, A_0)\; d\mu_{C^{loc}}(A_0)}{\int \chi^*(\Theta, A_0)\; d\mu_{C^{loc}}(A_0)} \tag{248}$$

We claim that this can be written as $C^{loc}(x,y)$ plus something tiny with good decay. This follows by another cluster expansion which we outline in Appendix D. For us the most useful way to state it is

$$C_\chi^{loc}(x,y) = C^{loc}(x,y) + \sum_{X \ni x,y} \delta K_{xy}(X) \tag{249}$$

where $|\delta K_{xy}(X)| \leq \mathcal{O}(e^{-\mathcal{O}(1) p(e_0)^2}) e^{-2\kappa|X|_1}$. Inserting this in (247) the first term contributes to P_Θ. The second term gives a contribution to $E^{**}(X)$ which is

$$\sum_{x,y \in X \cap \Theta} J_\mu^{(1)}(x) J_\mu^{(1)}(y) \delta K_{xy}(X) \tag{250}$$

and this has the bound $\mathcal{O}(e_0^{4-\epsilon} e^{-\kappa|X|_1})$ as claimed.

The treatment of the other terms in (246) is similar in each case splitting into a contribution to P_Θ and a contribution to E^{**}. The fermion propagator must also be localized with an expansion (see lemma 16)

$$\Gamma^{loc}(\tilde{A}; x, y) = \sum_{X \ni x,y} \Gamma_X^{loc}(\tilde{A}; x, y) \tag{251}$$

for its contribution to $E^{**}(X)$.

Finally consider the zeroth order term $\log Z(0)$. Again we use (240): $\log \mathcal{Z}(0) = \sum_X E(0,X)$. Now there is no potential. The only contributions to $E(0,X)$ are from the characteristic functions. This means lemma 8 can be modified to obtain a factor $\mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2})$ instead of $\mathcal{O}(e_0 p(e_0))$. Hence $E(0,X)$ is $\mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2}) e^{-\kappa|X|_1}$. These terms contribute to $E^{**}(X)$.

4.6 final adjustments

Assembling the results of the previous two sections we have for the small field region

$$\mathcal{Z}^{\dagger} = \exp\left(P_{\Theta} + \sum_{X\cap\Theta\neq\emptyset} E^{**}(X) \sum_{X\cap\Theta\neq\emptyset, X\subset(\Theta'')^c} B^{\#}(X) + \sum_{X\cap\Theta\neq\emptyset} R'(X) \right) \tag{252}$$

where $R'(X) = R^{\#}(X) + R^{*}(X)$.

It will be convenient to remove the R' from the small field region. It is possible because R' is so tiny. We make another Mayer expansion and write

$$\exp\left(\sum_{X\cap\Theta\neq\emptyset} R'(X) \right) = \sum_{\{X_i\}} \prod_i (e^{R'(X_i)} - 1) = \sum_S U(S) \tag{253}$$

where $\{X_i\}$ are distinct connected sets and where

$$U(S) = \sum_{\{X_i\}:\cup X_i = S} \prod_i (e^{R'(X_i)} - 1) \tag{254}$$

The function $U(S)$ factors over its connected components each one of which must intersect Θ. From the bound on $R'(X)$ we have for S connected

$$\|U(S)\|_{h_1} \leq \mathcal{O}(e^{-r(e_0)/M_1}) e^{-\mathcal{O}(1)\kappa|S|} \tag{255}$$

This is sufficient to control the sum over S. Now we write

$$\sum_S U(S) = \sum_{\Upsilon\subset\Theta} \left(\sum_{S:\Theta - S = \Upsilon} U(S) \right) \equiv \sum_{\Upsilon\subset\Theta} \mathcal{U}(\Upsilon^c) \tag{256}$$

Let us return to the full fluctuation integral (148). This can now be written

$$\tilde{\Xi}_{\Lambda} = \sum_{\Upsilon\subset\Theta\subset\Lambda'} \mathcal{G}_{\Theta,\Upsilon} \quad \exp\left(P_{\Theta} + \sum_{X\cap\Theta\neq\emptyset} E^{**}(X) \right) \tag{257}$$

where we have defined

$$\mathcal{G}_{\Theta,\Upsilon} = \mathcal{T}(\Theta^c) \exp\left(\sum_{X\cap\Theta\neq\emptyset, X\subset(\Theta'')^c} B^{\#}(X) \right) \mathcal{U}(\Upsilon^c) \tag{258}$$

We make the inverse transformation $A_0 \to A_0 - [H_1^{loc} A]_{\Omega'}$ in Λ^c and similarly for fermions. This does not affect the exponential and changes $\mathcal{G}_{\Theta,\Upsilon}$ to $\mathcal{G}'_{\Theta,\Upsilon}$ whence

$$\tilde{\Xi}'_{\Lambda} = \sum_{\Upsilon\subset\Theta\subset\Lambda'} \mathcal{G}'_{\Theta,\Upsilon} \quad \exp\left(P_{\Theta} + \sum_{X\cap\Theta\neq\emptyset} E^{**}(X) \right) \tag{259}$$

Next we scale replacing A by $A_{1,L}$, etc. to obtain

$$\Xi_{1,\Lambda} = \sum_{\Upsilon \subset \Theta \subset \Lambda'} \mathcal{G}_{1,\Theta,\Upsilon} \quad \exp\left(\mathcal{P}_{1,L^{-1}\Theta} + \sum_{Y \cap L^{-1}\Theta \neq \emptyset} E_1(Y) \right) \tag{260}$$

where $\mathcal{G}_{1,\Theta,\Upsilon}$ is the scaled version of $\mathcal{G}'_{\Theta,\Upsilon}$. We have also defined

$$\begin{aligned} \mathcal{P}_{1,L^{-1}\Theta}(\psi_1(\mathcal{A}_1),\mathcal{A}_1) =& P_\Theta([\psi_1(\mathcal{A}_1)]_L, \mathcal{A}_{1,L}) \\ E_1(Y,\psi_1(\mathcal{A}_1),\mathcal{A}_1) =& \sum_{X: \bar{X}^L = LY, X\cap\Theta\neq\emptyset} E^{**}(X,[\psi_1(\mathcal{A}_1)]_L,\mathcal{A}_{1,L}) \end{aligned} \tag{261}$$

Here $\bar{X}^L$ is the smallest union of of LM_1 blocks containing X. Explicitly we have for $S \subset \mathbb{T}^{-1}_{N+M-1}$

$$\begin{aligned} &\mathcal{P}_{1,S}(\tilde{\Psi}(\tilde{A}),\tilde{A}) \\ =&\frac{1}{2}L^{-6}\sum_{x,y\in S}\mathcal{J}^{(1)}_\mu(x)G^{loc}_1(x,y)\mathcal{J}^{(1)}_\mu(y) - \frac{1}{2}L^{-4}\sum_{x\in S}\mathcal{J}^{(2)}_{\mu,\mu}(x,x)G^{loc}_1(x,x) \\ &+\frac{1}{2}L^{-6}\sum_{x,y,z,w\in S}\bar{\mathcal{K}}^{(1)}_\mu(z,x)S^{loc}_1(\mathcal{A}_1;z,w)\mathcal{K}^{(1)}_\mu(w,y)\ G^{loc}_1(x,y) \\ &-\frac{1}{2}L^{-6}\sum_{x,y,z,w\in S}\mathcal{K}^{(1)}_\mu(z,x)S^{loc}_1(\mathcal{A}_1;z,w)\bar{\mathcal{K}}^{(1)}_\mu(w,y)\ G^{loc}_1(x,y) \\ &-L^{-6}\sum_{x,y,z,z',w,w'\in S} tr\left(\mathcal{L}^{(1)}_\mu(z,z',x)S^{loc}_1(\mathcal{A}_1;z',w')\mathcal{L}^{(1)}_\mu(w',w,y)S^{loc}_1(\mathcal{A}_1;w,z)\right)G^{loc}_1(x,y) \\ &-\frac{1}{2}L^{-4}\sum_{x,y,z,z'\in S} tr\left(\mathcal{L}^{(2)}_\mu(z,z',x,x)S^{loc}_1(\mathcal{A}_1;z',z)\right)G^{loc}_1(x,x) \\ &-L^{-3}\sum_{x\in S} :\bar{\psi}_1(\mathcal{A}_1,x)\ \delta m_1\ \psi(\mathcal{A}_1,x):_{\hat{S}_1-\mathcal{S}^{loc}_1(\mathcal{A}_1)} -\delta c E'_1|S| \end{aligned} \tag{262}$$

Here $\hat{S}_1 = (D(0)+m_1)^{-1}, m_1 = Lm_0, \delta m_1 = L\delta m_0$, and $\delta\mathcal{E}'_1 = L^3\delta\mathcal{E}_0$. The vertices $\mathcal{J}^{(n)},\mathcal{K}^{(n)},\mathcal{L}^{(n)}$ are the scaled versions of $J^{(n)},K^{(n)},L^{(n)}$. For example

$$\mathcal{J}^{(1)}_\mu(x,\psi_1(\mathcal{A}_1),\mathcal{A}_1) = L^{5/2}J^{(1)}_\mu(Lx,[\psi_1(\mathcal{A}_1)]_L,\mathcal{A}_{1,L}) \tag{263}$$

In general $J^{(n)},K^{(n)},L^{(n)}$ have the scaling factors $L^{2+\frac{1}{2}n}, L^{1+\frac{1}{2}n}, L^{\frac{1}{2}n}$. With this choice and $e_1 = L^{1/2}e_0$ we have that $J^{(n)},K^{(n)},L^{(n)}$ are $\mathcal{O}(e_1^n)$. We have also introduced

$$\begin{aligned} G^{loc}_1(x,y) =& LC^{loc}(Lx,Ly) \\ S^{loc}_1(\mathcal{A}_1;x,y) =& L^2\Gamma^{loc}_0(\mathcal{A}_{1,L};Lx,Ly) \end{aligned} \tag{264}$$

which are local approximations to the propagators $G_1, S_1(\mathcal{A}_1)$ defined earlier

5 Summary

Now insert the expression (260) for the fluctuation integral into our expansion (121) and obtain the density on $\mathbb{T}^0_{N+M-1}$

$$\begin{aligned}\rho_1(\Psi_1, A_1) =& c_0 e^{-\delta E_1} \sum_{\Omega,\tilde{\Lambda},\Theta,\Upsilon} \int d\Psi_0 dA_0 \ \zeta_{1,\Omega,\tilde{\Lambda}} \ \chi_{1,\Omega,\tilde{\Lambda}} \ \mathcal{G}_{1,\Theta,\Upsilon} \\ & \exp\left(-\frac{a}{2L^2}|A_{1,L} - QA_0|^2 - \frac{1}{2}(A_0, (-\Delta + \mu_0^2)A_0)\right) \\ & \exp\left(-\frac{a}{L}|\Psi_{1,L} - Q_{e_0}(\hat{A}_1)\Psi_0|^2 - (\bar{\Psi}_0, (D_{e_0}(\hat{A}_1) + m_0)\Psi_0)\right) \\ & \exp\left(\mathcal{P}_{1,L^{-1}\Theta} + \sum_{X\cap L^{-1}\Theta \neq \emptyset} E_1(X)\right) \chi_1(L^{-1}\Omega'', A_1)\end{aligned} \tag{265}$$

The sum is over decreasing sets $\Omega \supset \tilde{\Lambda} \supset \Theta \supset \Upsilon$ (which however are not the only restrictions). The factor $\zeta_{1,\Omega,\tilde{\Lambda}} \ \chi_{1,\Omega,\tilde{\Lambda}} \ \mathcal{G}_{1,\Theta,\Upsilon}$ supplies the convergence factors for the sums and is localized in Υ^c. The function $\mathcal{P}_1 + \sum_X E_1(X)$ is the effective action for the small field region with second order perturbation theory isolated.

This completes the treatment of the first step. In next paper we take these expressions as a starting point and iterate the operations we have performed. After k steps we are on the smaller torus $\mathbb{T}_{N+M-k}$ and we have an expansion similar to the above now with $4k$ decreasing sums over regions. In the new small field we have an effective action $\mathcal{P}_k + \sum_X E_k(X)$. The function $\mathcal{P}_k$ is second order in a running coupling constant $e_k = L^{-(N-k)/2}e$. It is given by the same diagrams as $\mathcal{P}_1$ but is expressed on the finer lattice $\mathbb{T}^{-k}_{N+M-k}$ instead of $\mathbb{T}^{-1}_{N+M-1}$.

As k gets large the ultraviolet singularities begin to appear again. In $\mathcal{P}_k$ the effect is denied by explicit renormalization cancellations. One can perhaps see how this will develop already in (262). In higher orders the effect is reflected in the fact that every time we scale down we potentially gain a factor of L^3 (see (261)). This is handled by the scaling properties of the fermion fields and the allowed growth of the coupling constant. In this respect our analysis is more like [11]. The case of no fermion fields is special. We take out the constant part with the energy counterterm and then locally we use gauge invariance to regard it as a function of the field strength dA. This has sufficiently good scaling properties to control the growth, see [15]. Thus the UV problems are handled. The IR problems are also disappearing as $k \to N$ since the volume is shrinking. Thus we will get an expression which is uniformly bounded in N.

A random walk expansions

We quote/sketch some results on the covariance operators. The original treatment for the Laplacian is due to Balaban [4] and the treatment for the Dirac operator can be found in Balaban, O'Carroll, and Schor [9], [10]. The operators on a unit lattice $\mathbb{T}^0_N$ are

$$\begin{aligned} C_\Lambda =&[\Delta^{\#}]^{-1}_\Lambda = [-\Delta + \mu_0^2 + \frac{a}{L^2} Q^T Q]^{-1}_\Lambda \\ \Gamma_\Lambda(A) =&[D^{\#}(A)]^{-1}_\Lambda = [D_{e_0}(A) + m_0 + \frac{a}{L} Q_{e_0}(-A)^T Q_{e_0}(A)]^{-1}_\Lambda \end{aligned} \tag{266}$$

Here Λ is a union of M_0-cubes centered on the M_0 lattice $\mathbb{T}^{M_0}_N$. The operators $[-\Delta]_\Lambda$ and $[D(A)]_\Lambda$ are defined by restricting to bonds in Λ. For the Laplacian this means Neumann boundary conditions.

First consider $C_{\mathcal{O}}, \Gamma_{\mathcal{O}}(A)$ where $\mathcal{O}$ is one of the sets $\mathcal{O}_j$ defined for $j \in T^{M_0}_N$ by

$$\mathcal{O}_j = \{x \in \Lambda : |x - j| \leq M_0\} \tag{267}$$

Here $|x-j| = \sup_\mu |x_\mu - j_\mu|$. These overlap and cover Λ. For interior points $\mathcal{O}_j$ is a $2M_0$ cube. Let $\|\partial A\|_{\mathcal{O}} = \sup_{\mathcal{O}} |\partial A|$

Lemma 13 *Let $e_0 M_0 L^2 \|\partial A\|_{\mathcal{O}}$ be sufficiently small. Then $\Gamma_{\mathcal{O}}(A)$, $C_{\mathcal{O}}$ exist and*

$$\begin{aligned} \|\Gamma_{\mathcal{O}}(A) f\|_2 \leq& \mathcal{O}(L^2) \|f\|_2 \\ \|C_{\mathcal{O}} f\|_2 \leq& \mathcal{O}(L^2) \|f\|_2 \end{aligned} \tag{268}$$

Proof. The bounds on $C_{\mathcal{O}}$ follow from the lower bound $(f, [-\Delta + aL^{-2} Q^T Q]_{\mathcal{O}} f) \geq \mathcal{O}(L^{-2}) \|f\|^2$. This in turn follows by bounding it below by a sum over L-squares with Neumann conditions. On each L-square $Q^T Q$ projects onto constants and on the complement of the constants the Laplacian is bounded below by $\mathcal{O}(L^{-2})$. See [4]. The bound for $\Gamma_{\mathcal{O}}(0)$ can be reduced to a bound on the Laplacian. See [10], lemma VI.4 for general idea.

lf A_0 is a constant (possibly large) we have on $\mathcal{O}$ that $A_0 = \partial \lambda_0$. Then by the gauge covariance

$$\Gamma_{\mathcal{O}}(A_0) = e^{ie_0 \lambda_0} \Gamma_{\mathcal{O}}(0) e^{-ie_0 \lambda_0} \tag{269}$$

Hence we have the result for constant background field.

Now in general for a field A on $\mathcal{O}$ we can write $A = \bar{A} + \delta A$ where $\bar{A} =$ constant is the average over $\mathcal{O}$ and $|\delta A| \leq M \|\partial A\|_{\mathcal{O}}$. Then put $V = D^{\#}_{\mathcal{O}}(\bar{A} + \delta A) - D^{\#}_{\mathcal{O}}(\bar{A})$ This has the contribution (34) from $D_{e_0}(A)$, and also a contribution from $Q_{e_0}(-A)^T Q_{e_0}(A)$. For $x \in B(y)$ we have the explicit formula

$$\left(Q(-A)^T Q(A) f\right)(x) = L^{-3} \sum_{\tilde{x} \in B(y)} \exp\left(ie_0 A(\Gamma_{xy} \cup \Gamma_{y\tilde{x}})\right) f(\tilde{x}) \tag{270}$$

Using these expressions we find

$$\|Vf\|_2 \leq \mathcal{O}(1)(e_0 M_0 \|\partial A\|_{\mathcal{O}})\|f\|_2 \tag{271}$$

Under our assumptions the inverse exists and is given by

$$\Gamma_{\mathcal{O}}(\bar{A} + \delta A) = \Gamma_{\mathcal{O}}(\bar{A}) \sum_{n-0}^{\infty} (-V\ \Gamma_{\mathcal{O}}(\bar{A}))^n \tag{272}$$

with the bound

$$\|\Gamma_{\mathcal{O}}(\bar{A} + \delta A) f\|_2 \leq \mathcal{O}(L^2)(1 - e_0 M_0 L^2 \|\partial A\|_{\mathcal{O}})^{-1} \|f\|_2 \leq \mathcal{O}(L^2)\|f\|_2 \tag{273}$$

This completes the proof.

We turn to the case of general Λ. Now inverses are obtained by a random walk expansion. A path ω in Λ is a sequence of lattice point $\omega = (j_0, j_1, \dots, j_n)$ which are neighbors in the sense that $|j_\alpha - j_{\alpha+1}| = 0$ or M_0 for any adjacent pair $(j_\alpha, j_{\alpha+1})$. The length of the path is $\ell(\omega) = n$. Each path ω also determines a sequence of cubes $(\mathcal{O}_{j_0}, \mathcal{O}_{j_1}, \cdots, \mathcal{O}_{j_n})$ as defined above. A path connects points x, y in the unit lattice if $x \in \mathcal{O}_{j_0}$ and $y \in \mathcal{O}_{j_n}$ in which case we write $\omega : x \to y$.

Lemma 14 *Let L^2/M_0 and $e_0 M_0 L^2 \|\partial A\|_{\mathcal{O}}$ be sufficiently small.*

1. *$\Gamma_\Lambda(A)$ and C_Λ exist.*

2. *We have the random walk expansion*

$$\begin{aligned} \Gamma_\Lambda(A) &= \sum_\omega \Gamma_{\Lambda,\omega}(A) \\ C_\Lambda &= \sum_\omega C_{\Lambda,\omega} \end{aligned} \tag{274}$$

   The kernels $\Gamma_{\Lambda,\omega}(A, x, y)$ and $C_{\Lambda,\omega}(x, y)$ vanish unless $\omega : x \to y$ and satisfy for some constant α

$$\begin{aligned} |C_{\Lambda,\omega}(x, y)| &\leq \mathcal{O}(L^2)(\frac{\alpha L^2}{M_0})^{\ell(\omega)} \\ |\Gamma_{\Lambda,\omega}(A, x, y)| &\leq \mathcal{O}(L^2)(\frac{\alpha L^2}{M_0})^{\ell(\omega)} \end{aligned} \tag{275}$$

3. *$\Gamma_{\Lambda,\omega}(A)$ depends on A only in $\mathcal{O}_{j_0} \cup \cdots \cup \mathcal{O}_{j_n}$.*

Proof. We give the results for the Dirac operator. First suppose Λ is the whole torus T^0_N and denote $\Gamma_\Lambda(A)$ as just $\Gamma(A)$. Choose smooth g with support in $\{x : |x| \leq \frac{2}{3}\}$ so that $g = 1$ on $\{x : |x| \leq \frac{1}{3}\}$ and so that $\sum_{i\in\mathbb{Z}^3} g^2(x-i) = 1$. Then for $j \in T^{M_0}_N$ define $h_j(x) = g((x-j)/M_0)$. Then h_j is supported in $\{x : |x-j| \leq \frac{2}{3}M_0\} \subset \mathcal{O}_j$ and $h_j = 1$ on $\{x : |x-j| \leq \frac{1}{3}M_0\}$ and $\sum_j h_j^2 = 1$. We define a parametrix by

$$\Gamma^*(A) = \sum_j h_j \Gamma_{\mathcal{O}_j}(A) h_j \tag{276}$$

Here things are arranged to avoid potential discontinuities of $\Gamma_{\mathcal{O}_j}(x,y)$ for (x,y) on the boundary of $\mathcal{O}_j$. Since $D^{\#}(A)\Gamma_{\mathcal{O}_j}(A) = I$ inside $\mathcal{O}_j$ we have

$$D^{\#}(A)\Gamma^*(A) = I - \sum_j R_j(A)\Gamma_{\mathcal{O}_j}(A)h_j \equiv I - R(A) \tag{277}$$

where

$$R_j(A) = -\left[D^{\#}(A), h_j\right] \tag{278}$$

The inverse of $D^{\#}(A)$ is now

$$\Gamma(A) = \Gamma^*(A)(I-R(A))^{-1} = \Gamma^*(A)\sum_{n=0}^{\infty} R(A)^n \tag{279}$$

with convergence in ℓ^2 provided $\|R(A)\| < 1$.

To see this we develop some estimates. For $R_j(A)$ we note that $\|[D_{e_0}(A), h_j]\| = \mathcal{O}(M_0^{-1})$ since $|\partial h_j| \leq \mathcal{O}(M_0^{-1})$. Furthermore we compute for $x \in B(y)$

$$\begin{aligned}&\frac{a}{L}\left([Q(-A)^TQ(A), h_j]f\right)(x)\\ &L^{-3}\sum_{\tilde{x}\in B(y)} \exp\left(ie_0A(\Gamma_{xy}\cup\Gamma_{y\tilde{x}})\right)\frac{a}{L}(h_j(x)-h_j(\tilde{x}))f(\tilde{x})\end{aligned} \tag{280}$$

Again this is bounded by $|\partial h_j|$ and so $(a/L)\|[Q(-A)^TQ(A), h_j]\| = \mathcal{O}(M_0^{-1})$. Combining these bounds we have $\|R_j(A)\| \leq \mathcal{O}(M_0^{-1})$. Note also that functions in the range of $R_j(A)$ have support in $\mathcal{O}_j$ since L is much smaller than M_0.

Now we have since $h_iR_j(A) = 0$ unless i,j are neighbors

$$\|h_iRf\| \leq \sum_j \|h_iR_j(A)\Gamma_{\mathcal{O}_j}(A)h_jf\| \leq \mathcal{O}(L^2M_0^{-1})\sum_{j:|i-j|\leq M_0}\|h_jf\| \tag{281}$$

After a Schwarz inequality we can replace the sum on the right by the expression $(\sum_{j:|i-j|\leq M_0}\|h_jf\|^2)^{1/2}$. Then

$$\|R(A)f\|^2 = \sum_i \|h_iR(A)f\|^2 \leq \mathcal{O}(L^4M_0^{-2})\sum_{i,j:|i-j|\leq M_0}\|h_jf\|^2 \leq \mathcal{O}(L^4M_0^{-2})\|f\|^2 \tag{282}$$

Hence $\|R(A)\| \leq \mathcal{O}(L^2 M_0^{-1}) < 1$ and (a.) is proved.

Now we can write $\Gamma(A)$ as a sum over random walks by inserting the definitions of $\Gamma^*(A)$ and $R(A)$ into (279) and obtaining

$$\begin{aligned} \Gamma(A) = & \sum_{n=0}^{\infty} \sum_{j_0, j_1, \ldots, j_n} (h_{j_0} \Gamma_{\mathcal{O}_{j_0}}(A) h_{j_0})(R_{j_1}(A) \Gamma_{\mathcal{O}_{j_1}}(A) h_{j_1}) \cdots (R_{j_n}(A) \Gamma_{\mathcal{O}_{j_n}}(A) h_{j_n}) \\ \equiv & \sum_{\omega} \Gamma_\omega(A) \end{aligned} \tag{283}$$

Here in the last step we notice that we get zero unless $j_\alpha, j_{\alpha+1}$ are neighbors.

By our previous estimates we have for some $\alpha = \mathcal{O}(1)$

$$\|\Gamma_\omega(A)\| \leq \mathcal{O}(L^2)(\alpha L^2 / M_0)^{\ell(\omega)} \tag{284}$$

Since we are on a unit lattice the same bound holds for $|\Gamma_\omega(A, x, y)|$. The restriction to $\omega : x \to y$ is obvious. Thus (b.) is proved and (c.) follows by inspection.

Now suppose consider general Λ. We replace h_j by $h_j^\Lambda \equiv \chi_\Lambda h_j$ and repeat the above argument with $[D^\#(A)]_\Lambda$ instead of $D^\#(A)$. This completes the proof.

Remark. If ω has no points on $\partial\Lambda$ then $C_{\Lambda,\omega}$ and $\Gamma_{\Lambda,\omega}(A)$ are independent of Λ.

Lemma 15 *Under the same assumptions with* $\beta = M_0^{-1}$ *we have for* $x, y \in \Lambda$.

$$\begin{aligned} |C_\Lambda(x, y)| \leq \mathcal{O}(L^2) exp(-\beta d(x, y)) \\ |\Gamma_\Lambda(A; x, y)| \leq \mathcal{O}(L^2) exp(-\beta d(x, y)) \end{aligned} \tag{285}$$

Also

$$|\Gamma_\Lambda(A; x, y) - \Gamma(A; x, y)| \leq \mathcal{O}(L^2) exp\left(-\beta(d(x, y) + d(x, \Lambda^c) + d(y, \Lambda^c))\right) \tag{286}$$

and similarly for $C_\Lambda(x, y)$.

Proof. A crude estimate is

$$\begin{aligned} \Gamma_\Lambda(A; x, y) \leq & \mathcal{O}(L^2) \sum_{\omega : x \to y} (\frac{\alpha L^2}{M_0})^{\ell(\omega)} \\ \leq & \mathcal{O}(L^2) \sum_n (\frac{\alpha L^2}{M_0})^n |\{\omega : x \to y : \ell(\omega) = n\}| \\ \leq & \mathcal{O}(L^2) \sum_n (\frac{27 \alpha L^2}{M_0})^n \leq \mathcal{O}(L^2) \end{aligned} \tag{287}$$

But the condition $\omega : x \to y$ means that the sum is restricted to $n \geq (d(x, y)/M_0) - 2$. Thus we can estimate $(\alpha L^2 M_0^{-1})^{n/2}$ by $\mathcal{O}(1) \exp(-d(x, y)/M_0)$ and still have another factor $(\alpha L^2 M_0^{-1})^{n/2}$ to estimate the sum as above.

For the second result proceed as follows. We write

$$\Gamma_\Lambda(A;x,y) - \Gamma(A;x,y) = \sum_{\omega:x\to y} \Gamma_{\Lambda,\omega}(A;x,y) - \Gamma_\omega(A;x,y) \tag{288}$$

But if ω has no boundary points we have $\Gamma_{\Lambda,\omega}(A,x,y) = \Gamma_\omega(A,x,y)$ and hence no contribution. Thus we can restrict to ω with boundary points and hence get the result for each term separately.

We will also need reblocked random walk expansions on a scale M_1 larger than M_0. We assume Λ is a union of M_1 blocks centered on $\mathbb{T}_N^{M_1}$ and we have

Lemma 16 *Under the same assumptions*

$$\begin{aligned} C_\Lambda &= \sum_{X\ni x,y} C_{\Lambda,X} \\ \Gamma_\Lambda(A) &= \sum_{X\ni x,y} \Gamma_{\Lambda,X}(A) \end{aligned} \tag{289}$$

where the sum is over connected unions of M_1-blocks X. The operator $\Gamma_{\Lambda,X}(A)$ depends on A only in X and the kernels $C_\Lambda(x,y), \Gamma_\Lambda(A,x,y)$ have support in $X \times X$. Furthermore

$$\begin{aligned} |C_{\Lambda,X}(x,y)| &\leq \mathcal{O}(1) e^{-\beta M_1 |X|_1} e^{-\beta d(x,y)} \\ |\Gamma_{\Lambda,X}(A,x,y)| &\leq \mathcal{O}(1) e^{-\beta M_1 |X|_1} e^{-\beta d(x,y)} \end{aligned} \tag{290}$$

Proof. Define

$$\Gamma_{\Lambda,X}(A,x,y) = \sum_{\substack{\omega:x\to y \\ \bar\omega = X}} \Gamma_{\Lambda,\omega}(A,x,y) \tag{291}$$

where $\bar\omega$ are the M_1 blocks intersecting $\mathcal{O}_{j_0} \cup \cdots \cup \mathcal{O}_{j_n}$. Now $\bar\omega$ cannot be very large without ω itself covering some substantial distance and one can show

$$M_0 \ell(\omega) \geq 9 M_1 (|\bar\omega|_1 - 8) \tag{292}$$

Using this for a lower bound on $\ell(\omega)$ we extract the factor $e^{-\beta M_1 |X|_1}$. The estimate now proceeds as before. This completes the proof.

We also want to consider local operators $C^{loc}_\Lambda(x,y)$ and $\Gamma^{loc}_\Lambda(A,x,y)$ defined by restricting the random walk expansion (274) to paths which stay within $r(e_0)/2$ of both x and y. Then we have

Lemma 17 *Under the same assumptions*

$$\begin{aligned} C_\Lambda - C^{loc}_\Lambda &= \sum_X \delta C_{\Lambda,X} \\ \Gamma_\Lambda(A) - \Gamma^{loc}_\Lambda(A) &= \sum_X \delta\Gamma_{\Lambda,X}(A) \end{aligned} \tag{293}$$

where

$$
\begin{aligned}
|\delta C_{\Lambda,X}(x,y)| \leq & \mathcal{O}(e^{-\beta r(e_0)}) e^{-\beta M_1 |X|_1} e^{-\beta d(x,y)} \\
|\delta \Gamma_{\Lambda,X}(A,x,y)| \leq & \mathcal{O}(e^{-\beta r(e_0)}) e^{-\beta M_1 |X|_1} e^{-\beta d(x,y)}
\end{aligned}
\tag{294}
$$

Proof. $\delta\Gamma_{\Lambda,X}(A,x,y)$ has an expression like (291) in which only paths with $\ell(\omega) \geq M_0^{-1} r(e_0)/2$ contribute. This enables us to extract the factor $e^{-\beta r(e_0)}$.

Finally we consider operators of the form $\partial C_\Lambda(s)/\partial s_Y$ as defined in the text in (159)

Lemma 18 *Let $\mathcal{L}(x,y,Y)$ is the length of the shortest tree through x,y and the centers of the blocks in Y. Then with a universal constant $\mathcal{O}(1)$ we have*

$$
|\frac{\partial C_\Lambda}{\partial s_Y}(x,y)| \leq \mathcal{O}(1) M_0^{-\mathcal{O}(1)|Y|_1} e^{-\beta \mathcal{L}(x,y,Y)} \tag{295}
$$

and similarly for fermions.

Proof. We can assume $Y \neq \emptyset$. We have $C_\Lambda(s,x,y) = \sum_{\omega : x \to y} s_\omega C_{\Lambda,\omega}(x,y)$. After the $\partial/\partial s_Y$ differentiation the only terms ω which survive are those with with $\ell(\omega) \geq 1$ and $\bar{\omega} \supset \Delta_x \cup \Delta_y \cup Y$ where Δ_x is the M_1 block containing x. This leads to

$$
|\frac{\partial C_\Lambda}{\partial s_Y}(x,y)| \leq \mathcal{O}(L^2) \sum_\omega{}' (\frac{\alpha L^2}{M_0})^{\ell(\omega)} \tag{296}
$$

The prime indicates the restricted sum over paths. Now $\ell(\omega) \geq |\bar{\omega}|_1/2 \geq |Y|_1/2 - 1$ enables us to extract a factor $M_0^{-\mathcal{O}(1)|Y|_1}$. (For the first inequality assume $|\bar{\omega}|_1 \geq 2$ and use $\ell(\omega) \geq |\bar{\omega}|_1 - 1 \geq |\bar{\omega}|/2$; check $|\bar{\omega}|_1 = 1$ separately). On the other hand by (292) and the fact that $\bar{\omega}$ is connected we have

$$
M_0 \ell(\omega) \geq 9 M_1 |\bar{\omega}| - \mathcal{O}(1) \geq 9 \mathcal{L}(\bar{\omega}) - \mathcal{O}(1) \geq \mathcal{O}(1) \mathcal{L}(\Delta_x \cup \Delta_y \cup Y) - \mathcal{O}(1) \tag{297}
$$

This enables us to extract a factor $\mathcal{O}(1) e^{-\beta \mathcal{L}(x,y,Y)}$.

B fermion norms and integrals

We consider the Grassman algebra generated by $\Psi_\alpha(x), \bar{\Psi}_\alpha(x)$ where (x, α) are space-time and spinor indices. Let ξ stand for $(0, \alpha, x)$ or $(1, \alpha, x)$ and define $\Psi(\xi)$ by $\Psi(0, \alpha, x) = \Psi_\alpha(x)$ and $\Psi(1, \alpha, x) = \bar{\Psi}_\alpha(x)$. Then the $\Psi(\xi)$ generate the algebra and any element can be uniquely written

$$F(\Psi) = \sum_n 1/r! \sum_{\xi_1, \dots, \xi_r} f_r(\xi_1, ..., \xi_r)\Psi(\xi_1)...\Psi(\xi_r) \tag{298}$$

where the coefficients f_r are totally antisymmetric functions. We define a norm $\|\cdot\|_h$ depending on a parameter $h > 0$ by (c.f. [12])

$$\|F\|_h = \sum_r \frac{h^r}{r!}\|f_r\|_1 \tag{299}$$

where $\|f_r\|_1$ is the ℓ_1 norm.

Lemma 19 $\|FG\|_h \leq \|F\|_h\|G\|_h$

Proof. $H = FG$ has the coefficients

$$h_r = \sum_{s+t=r} \frac{r!}{s!t!} \ \mathrm{alt}(f_s \otimes g_t) \tag{300}$$

and hence

$$\|h_r\|_1 \leq \sum_{s+t=r} \frac{r!}{s!t!} \ \|f_s\|_1\|g_t\|_1 \tag{301}$$

Now multiplying by $h^r/r!$ and summing over r gives the result.

Next consider transformations of the form $F'(\Psi) = F(A\Psi)$ where $(A\Psi)(\xi) = \sum_{\xi'} A(\xi, \xi')\Psi(\xi')$. We can estimate the effect in terms of the norm

$$\|A\|^{(1)} = \sup_\xi \sum_{\xi'} |A(\xi, \xi')| \tag{302}$$

Lemma 20 *Let* $F'(\Psi) = F(A\Psi)$. *If* $h'\|A\|^{(1)} \leq h$ *then*

$$\|F'\|_{h'} \leq \|F\|_h \tag{303}$$

Proof. F' has coefficients

$$f'_r(\xi'_1, \dots, \xi'_r) = \sum_{\xi_1, \dots, \xi_r} f_r(\xi_1, \dots, \xi_n) \prod_{i=1}^r A(\xi_i, \xi'_i) \tag{304}$$

Hence $\|f_r'\| \leq (\|A\|^{(1)})^r \|f_r\|$. Now multiply by $(h')^r/r!$ and sum over r to get the result.

Now we distinguish between $\Psi(x), \bar{\Psi}(x)$. We use a notation in which the spinor indices are suppressed, i.e. x_i really means the pair (x_i, α_i). The general element (298) can then be uniquely written be in the form:

$$\begin{aligned} &F(\Psi, \bar{\Psi}) \\ =&\sum_{n,m} \frac{1}{n!m!} \sum_{\substack{x_1,\dots,x_n \\ \bar{x}_1,\dots,\bar{x}_m}} f_{n,m}(x_1, ..., x_n, \bar{x}_1, \dots, \bar{x}_m)\Psi(x_1)\dots\Psi(x_n)\bar{\Psi}(\bar{x}_1)\dots\bar{\Psi}(\bar{x}_m) \\ \equiv&\sum_{n,m} \frac{1}{n!m!} \sum_{X_n, \bar{X}_m} f_{n,m}(X_n, \bar{X}_m)\Psi(X_n)\bar{\Psi}(\bar{X}_m) \end{aligned} \tag{305}$$

where the coefficients $f_{n,m}$ are antisymmetric separately in $X_1 = (x_1, ..., x_n)$ and $\bar{X}_m = (\bar{x}_1, ..., \bar{x}_m)$. We have in fact

$$f_{n,m}(x_1, ..., x_n, \bar{x}_1, \dots, \bar{x}_m) = f_{n+m}((0, x_1), ..., (0, x_n), (1, \bar{x}_1), \dots, (1, \bar{x}_m)) \tag{306}$$

We usually consider elements in which only terms with $n = m$ contribute.

Now the norm (299) can now be written

$$\|F\|_h = \sum_{n,m} \frac{h^{n+m}}{n!m!} \|f_{n,m}\|_1 \tag{307}$$

A fermion Gaussian "measure" with non-singular covariance $\Gamma = D^{-1}$ can be defined by

$$d\mu_\Gamma(\Psi, \bar{\Psi}) = \frac{e^{-(\bar{\Psi}, D\Psi)} d\Psi d\bar{\Psi}}{\int e^{-(\bar{\Psi}, D\Psi)} d\Psi d\bar{\Psi}} \tag{308}$$

Then one can consider integrals of the form $\int F d\mu_\Gamma$. Terms with $n \neq m$ give zero while terms with $n = m$ are integrated by

$$\int \Psi(x_1)\bar{\Psi}(\bar{x}_1)\dots\Psi(x_n)\bar{\Psi}(\bar{x}_n)\ d\mu_\Gamma(\Psi, \bar{\Psi}) = \det\left\{\Gamma(x_i, \bar{x}_j)\right\} \tag{309}$$

For the proof see for example [17] whose conventions we have adopted. This identity can also be used to define $d\mu_\Gamma$ when Γ is singular.

To estimate these integrals we introduce

$$\|\Gamma\|^{(2)} = \left(\sup_x \sum_{\bar{x}} |\Gamma(x, \bar{x})|^2\right)^{1/2} \tag{310}$$

Lemma 21 *If* $\sqrt{\|\Gamma\|^{(2)}} \leq h$ *then*

$$|\int F(\Psi,\bar{\Psi})d\mu_{\Gamma}(\Psi,\bar{\Psi})| \leq \|F\|_h \tag{311}$$

Proof. Let σ_n be the sign of the permutation that takes $\Psi(x_1)\dots\Psi(x_n)\bar{\Psi}(\bar{x}_1)\dots\bar{\Psi}(\bar{x}_n)$ to $\Psi(x_1)\bar{\Psi}(\bar{x}_1)\dots\Psi(x_n)\bar{\Psi}(\bar{x}_n)$. Then the integral is evaluated as

$$\int F d\mu_{\Gamma} = \sum_n \frac{\sigma_n}{(n!)^2} \sum_{\substack{x_1,\dots,x_n\\ \bar{x}_1,\dots,\bar{x}_n}} f_{n,n}(x_1,...,x_n,\bar{x}_1,\dots,\bar{x}_n)\det\{\Gamma(x_i,\bar{x}_j)\} \tag{312}$$

By Hadamard's inequality [18] we have

$$|\det\{\Gamma(x_i,\bar{x}_j)\}| \leq (\|\Gamma\|^{(2)})^n \leq h^{2n} \tag{313}$$

and so the result:

$$|\int F d\mu_{\Gamma}| \leq \sum_n \frac{h^{2n}}{(n!)^2}\|f_{n,n}\|_1 \leq \|F\|_h \tag{314}$$

Now suppose our Grassman algebra is generated by two sets of basis elements $\Psi(y),\bar{\Psi}(y)$ and $\Psi'(x),\bar{\Psi}'(x)$. The general element has the form

$$\begin{aligned} &F(\Psi,\bar{\Psi},\Psi',\bar{\Psi}') \\ &= \sum_{n,m,\ell,k} \frac{1}{n!m!\ell!k!} \sum_{Y_n,\bar{Y}_m,X_\ell,\bar{X}_k} f_{n,m,\ell,k}(Y_n,\bar{Y}_m,X_\ell,\bar{X}_k)\Psi(Y_n)\bar{\Psi}(\bar{Y}_m)\Psi'(X_\ell)\bar{\Psi}'(\bar{X}_k) \end{aligned} \tag{315}$$

where $f_{n,m,\ell,k}$ is anti-symmetric separately in each of the four groups of variables. The norm is now

$$\|F\|_h = \sum_{n,m,\ell,k} \frac{h^{n+m+\ell+k}}{n!m!\ell!k!}\|f_{n,m,\ell,k}\|_1 \tag{316}$$

Gaussian integrals with respect to $\Psi',\bar{\Psi}'$ only are defined in the obvious way. They are estimated as follows:

Lemma 22 *If* $h', \sqrt{\|\Gamma\|^{(2)}} \leq h$ *then*

$$\|\int F(\Psi,\bar{\Psi},\Psi',\bar{\Psi}')d\mu_{\Gamma}(\Psi',\bar{\Psi}')\|_{h'} \leq \|F\|_h \tag{317}$$

Proof. The integral is evaluated as

$$\sum_{n,m,\ell} \frac{\sigma_\ell}{n!m!(\ell!)^2} \sum_{Y_n,\bar{Y}_m,X_\ell,\bar{X}_\ell} f_{n,m,\ell,\ell}(Y_n,\bar{Y}_m,X_\ell,\bar{X}_\ell)\ \det\{\Gamma(x_i,\bar{x}_j)\}\ \Psi(Y_n)\bar{\Psi}(\bar{Y}_m) \tag{318}$$

By Hadamard's inequality the determinant is less than $(\|\Gamma\|^{(2)})^\ell$ and this expression has h'-norm dominated by

$$\sum_{n,m,\ell} \frac{(h')^{n+m}(\|\Gamma\|^{(2)})^\ell}{n!m!(\ell!)^2}\|f_{n,m,\ell,\ell}\|_1 \leq \|F\|_h \tag{319}$$

C spacetime split

Let S be a finite set (e.g. one of our tori) and let Λ be a subset (e.g. a small field region). Suppose we have a Gaussian integral on $\mathbb{R}^S$ defined by a positive self-adjoint operator T on $\mathbb{R}^S$. We want to carry out the integral over $\mathbb{R}^\Lambda$ first. This is accomplished by:

Lemma 23

$$\int_{\mathbb{R}^S} H(A_{\Lambda^c})F(A)\exp\left(-\frac{1}{2}(A,TA)\right)dA = \int_{\mathbb{R}^S} H(A_{\Lambda^c})\tilde{F}(A_{\Lambda^c})\exp\left(-\frac{1}{2}(A,TA)\right)dA \tag{320}$$

where

$$\tilde{F}(A_{\Lambda^c}) = \int_{\mathbb{R}^\Lambda} F(A)d\mu_{C_\Lambda,\alpha_\Lambda}(A_\Lambda) \tag{321}$$

and $\mu_{C_\Lambda,\alpha_\Lambda}$ *is the Gaussian measure with covariance* $C_\Lambda = T_\Lambda^{-1}$ *and mean* $\alpha_\Lambda = -T_\Lambda^{-1}T_{\Lambda\Lambda^c}A_{\Lambda^c}$

Remark. $\tilde{F}(A_{\Lambda^c})$ is the conditional expectation of $F(A)$ with respect to the variables A_{Λ^c}.

Proof. In (A,TA) we write $T = T_{\Lambda^c} + T_{\Lambda^c\Lambda} + T_{\Lambda\Lambda^c} + T_\Lambda$ where $T_{\Lambda^c\Lambda} = \chi_{\Lambda^c}T\chi_\Lambda$, etc. The cross terms are eliminated by the transformation $A_\Lambda \to A_\Lambda + \alpha_\Lambda$, $A_{\Lambda^c} \to A_{\Lambda^c}$ which we also write as $A \to A + \alpha_\Lambda$. Then the left side of (320) becomes

$$\int dA_{\Lambda^c}H(A_{\Lambda^c})\ \exp(-\frac{1}{2}(A,R_{\Lambda_c}A))\ \left(\int F(A+\alpha_\Lambda)\exp(-\frac{1}{2}(A,T_\Lambda A))dA_\Lambda\right) \tag{322}$$

where $R_{\Lambda^c} = T_{\Lambda^c} - T_{\Lambda^c\Lambda}T_\Lambda^{-1}T_{\Lambda\Lambda^c}$. If we divide by $\int\exp(-(\Phi,T_\Lambda\Phi))d\Phi_\Lambda$ the term in parentheses is identified as $\tilde{F}(A_{\Lambda^c})$ and we have

$$\int dA_{\Lambda^c}H(A_{\Lambda^c})\tilde{F}(A_{\Lambda^c})\ \exp(-\frac{1}{2}(A,R_{\Lambda_c}A))\ \left(\int \exp(-\frac{1}{2}(A,T_\Lambda A))dA_\Lambda\right) \tag{323}$$

Now reverse the first step to get the right side of (320) . This completes the proof.

The above result is for bosons. For fermions suppose we have Grassman variables $\bar{\Psi},\Psi$ indexed by S and a Gaussian measure determined by an operator T on $\mathbb{R}^S$. We assume that $T_\Lambda = \chi_\Lambda T\chi_\Lambda$ is non-singular.

Lemma 24

$$\begin{aligned}&\int H(\bar{\Psi}_{\Lambda^c},\Psi_{\Lambda^c})F(\bar{\Psi},\Psi)\exp\left(-(\bar{\Psi},T\Psi)\right)d\bar{\Psi}d\Psi\\ =&\int H(\bar{\Psi}_{\Lambda^c},\Psi_{\Lambda^c})\tilde{F}(\bar{\Psi}_{\Lambda^c},\Psi_{\Lambda^c})\exp\left(-(\bar{\Psi},T\Psi)\right)d\bar{\Psi}d\Psi\end{aligned} \tag{324}$$

where

$$\tilde{F}(\bar{\Psi}_{\Lambda^c}, \Psi_{\Lambda^c}) = \int F(\bar{\Psi}, \Psi) d\mu_{\Gamma_\Lambda, \beta_\Lambda, \bar{\beta}_\Lambda}(\bar{\Psi}_\Lambda, \Psi_\Lambda) \tag{325}$$

is the the Gaussian integral over $\bar{\Psi}_\Lambda, \Psi_\Lambda$ *with covariance* $\Gamma_\Lambda = T_\Lambda^{-1}$ *and mean* $\beta_\Lambda = -T_\Lambda^{-1} T_{\Lambda\Lambda^c} \Psi_{\Lambda^c}$ *and* $\bar{\beta}_\Lambda = -(T_\Lambda^{-1})^T (T_{\Lambda^c\Lambda})^T \bar{\Psi}_{\Lambda^c}$*.*

Proof. Follow the proof of the previous lemma. The transformation is now $\Psi_\Lambda \to \Psi_\Lambda + \beta_\Lambda$ and $\bar{\Psi}_\Lambda \to \bar{\Psi}_\Lambda + \bar{\beta}_\Lambda$ and the Gaussian integral is identified/defined as

$$\tilde{F}(\bar{\Psi}_{\Lambda^c}, \Psi_{\Lambda^c}) = \frac{\int F(\bar{\Psi} + \bar{\beta}_\Lambda, \Psi + \beta_\Lambda) \exp\left(-(\bar{\Psi}, T_\Lambda \Psi)\right) d\bar{\Psi}_\Lambda d\Psi_\Lambda}{\int \exp\left(-(\bar{\Psi}, T_\Lambda \Psi)\right) d\bar{\Psi}_\Lambda d\Psi_\Lambda} \tag{326}$$

The denominator is non-zero by the assumption that T_Λ is non-singular.

D two point function

We study the fluctuation two point function with characteristic functions present as defined by

$$C_\chi(x,y) = \frac{\int A_{0,\mu}(x) A_{0,\mu}(y) \chi^*(\Theta, A_0) \ d\mu_C(A_0)}{\int \chi^*(\Theta, A_0) \ d\mu_C(A_0)} \tag{327}$$

where χ^* is defined in (84) The following results also hold with C replaced by C^{loc}

Lemma 25 *We have with a universal* $\mathcal{O}(1)$ *in the exponent*

1. $|C_\chi(x,y)| \leq \mathcal{O}(1) \exp(-\mathcal{O}(1) M_1^{-1} d(x,y))$
2. $|C_\chi(x,y) - C(x,y)| \leq \mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2}) \exp(-\mathcal{O}(1) M_1^{-1} d(x,y))$

Proof. We use a simpler version of the cluster expansion of theorem 1 to which we refer for more details.

Start with the numerator in C_χ. Replace the characteristic function by $\sum_{P \subset \Theta} \zeta^*(P)$ and then break up the measure by introducing the s-parameters in the complement of $\Delta_x \cup \Delta_y \cup P$. ($\Delta_x = M_1$-block containing x). We find an expansion

$$\int A_{0,\mu}(x) A_{0,\mu}(y) \chi^*(\Theta, A_0) \ d\mu_C(A_0) = \sum_{\{Z_i\}} \prod_i K(Z_i) \tag{328}$$

where the sum is over collections of disjoint connected sets Z_i intersecting $\Delta_x \cup \Delta_y \cup \Theta$. In fact the points x, y must be contained in a single Z_i, otherwise the contribution vanishes since we are integrating an odd function. Call this distinguished polymer Z^*. We have

$$K(Z^*) = \sum_{P, Y \to Z^*} \int ds_Y \frac{\partial}{\partial s_Y} [\int A_{0,\mu}(x) A_{0,\mu}(y) \ \zeta^*(P) \ d\mu_{C(s)}(A_0)] \tag{329}$$

The sum is over disjoint $(\Delta_x \cup \Delta_y) \cup P \cup Y = Z^*$. Given κ this satisfies $|K(Z^*)| \leq \mathcal{O}(1)e^{-\kappa|Z^*|_1}$ provided M_0, M_1 are large enough. If Z does not contain x, y then $K(Z)$ is given by the same expression with no A_0-fields. Now P cannot be empty and using (174) we get $|K(Z)| \leq \mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2})e^{-\kappa|Z|_1}$. We separate off the distinguished polymer and write for (328)

$$\sum_{Z^* \ni x,y} K(Z^*) \left(\sum_{\{Z_i\} \text{ in } (Z^{**})^c} \prod_i K(Z_i) \right) = \sum_{Z^* \ni x,y} K(Z^*) \exp \left(\sum_{X \subset (Z^{**})^c} E(X) \right) \tag{330}$$

where Z^{**} is Z^* enlarged by a corridor of M_1-blocks. Here we take advantage of the small norm in $(Z^{**})^c$ to exponentiate. We have $|E(X)| \leq \mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2})e^{-\kappa|X|_1}$.

Now do the same thing without the fields and obtain

$$\int \chi^*(\Theta, A_0) \; d\mu_C(A_0) = \exp \left(\sum_X E(X) \right) \tag{331}$$

For the ratio we have

$$C_\chi(x,y) = \sum_{Z^* \ni x,y} K(Z^*) \exp \left(\sum_{X \cap Z^{**} \neq \emptyset} E(X) \right) \equiv \sum_{Z^* \ni x,y} K'(Z^*) \tag{332}$$

Using $|\sum_X E(X)| \leq \mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2})|Z^*|$ and the bound on $K(Z^*)$ we get $|K'(Z^*)| \leq \mathcal{O}(1)e^{-\frac{1}{2}\kappa|Z^*|_1}$ This controls the sum over Z^* and also yields the decay factor. Thus the first result is established.

For the second result we make a cluster expansion for $C(x,y)$. Now only polymers containing x, y contribute at all and we have

$$C(x,y) = \int A_{\mu,0}(x) A_{\mu,0}(y) \; d\mu_C(A_0) = \sum_{Z^* \ni xy} K^0(Z^*) \tag{333}$$

where

$$K^0(Z^*) = \sum_{Y \to Z^*} \int ds_Y \frac{\partial}{\partial s_Y} [\int A_{\mu,0}(x) A_{\mu,0}(y) \; d\mu_{C(s)}(A_0)] \tag{334}$$

The difference is expressed as

$$C_\chi(x,y) - C(x,y) = \sum_{Z^* \ni x,y} \left(K'(Z^*) - K^0(Z^*) \right) \equiv \sum_{Z^* \ni x,y} \delta K(Z^*) \tag{335}$$

We claim that

$$|\delta K(Z^*)| \leq \mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2})e^{-\frac{1}{2}\kappa|Z^*|_1} \tag{336}$$

which will give the result. If we replace the exponential in $K'(Z^*)$ by one, the difference is a term with this estimate. Thus it suffices to look at

$$K(Z^*) - K^0(Z^*) = \sum_{P,Y \to Z^*, P \neq \emptyset} \int ds_Y \frac{\partial}{\partial s_Y} [\int A_{\mu,0}(x) A_{\mu,0}(y)\ \zeta^*(P) d\mu_{C(s)}(A_0)] \tag{337}$$

Here we use $\zeta^*(\emptyset) = 1$. The new condition $P \neq \emptyset$ allows us to extract a factor $\mathcal{O}(e^{-\mathcal{O}(1)p(e_0)^2})$ and the rest of the bound goes as before. This completes the proof.
